INDEX FOR 1848.

A.

Abdominal Viscera, Malposition of, 585
Abortion, 592
Abscess of the Bladder, 187
..... of the Brain, 487
..... of the Liver, 47
..... between Liver and Diaphragm, 189
..... of the Pancreas, 20
..... Fæcal, Cases of, 478
..... Mammary, a point in the Treatment of, 161
..... Submammary, discharged through the Trachea, 163
..... Sub-peritoneal, 590
Absorption of Insoluble Substances, 555
Académie de Médecine, Paris, 21, 50, 240, 272, 302, 357, 414, 501, 582, 637
..... des Sciences, Paris, 21, 51, 241, 272, 302, 414, 501
Acetate of Lead, in Tympanites, 54
Actions against a Railway Company for Professional Services, 217, 276, 307, 712
Adams, Dr., On Burns, &c., 42
..... N., Tracheotomy in Laryngitis, 643
Address, Retrospective, delivered at the Seventh Anniversary of the Reading Pathological Society, 561, 589
Æther and Chloroform, Comparative Effects of, 241, 272
Ætherization, Influence of, on the Mortality of Surgical Operations, 642
Air-passages, Foreign Bodies in, 191, 529
Albuminuria, 505, 593
Allan, J., Observations on Hernia, 512
American Medical Association, Deputation from, 457, 460
Ammonia as an Antidote to Anæsthetic Agents, 401
..... Inhalation of, in Hiccup, 669
Amputation, Comparative Mortality from Phlebitis and Secondary Hæmorrhage, after the Flap and Circular Operations, 109
.... at the Hip-joint, 642
..... of Thigh, 606
..... under the Influence of Chloroform, 61
Amyot, T. E., Case Illustrative of the Effects of Overloaded Bowels, 232
Anæmia, 19
Anæsthesia, Local, Notes on its Artificial Production by Chloroform, &c., 365
Anæsthetic Agents, Ammonia as an Antidote to, 401
..... in Surgical Operations, Observations on, 425
Anæsthetic Midwifery in America, 669
Anasarca, with Albuminous Urine, in an Infant Ten Weeks old, 511
Ancell, H., Principles of Medical Legislation, Reply to Mr. Nunneley, 250
Anderton, C., Perforating Ulcer of the Colon; Mechanical Occlusion by Hardened Fæces, 288
Aneurism of the Aorta, 20, 48, 356, 664
..... of the Carotid Artery, 579
..... Capillary, Extirpation of, by Ligature, 276
..... Carotid, Tumour of the Neck simulating, 137
..... Dissecting, 304
..... Subclavian, 378, 516, 544
..... Varicose, 176
Angina, 589
..... Venesection of the Ranine Veins in, 442
Animal Heat, Experiments on, 218
Anniversary Meeting of the Provincial Medical and Surgical Association, 280, 336, 364, 449
Antimony, Sesqui-Chloride of, Poisoning by, 164
Anus, Fissure of, New Method of Treatment in, 585
Aorta, Aneurism of, 20, 48, 356, 664
..... Anomaly of, 161
..... Abdominal, Compression of, in Uterine Hæmorrhage, 188, 220
Aortic Valves, Diseased, 355, 505
Aphonia, curable by Inhalation of the Fumes of Benzoin, 161
Aphthæ, 304
Appointments, 28, 56, 84, 112, 140, 167, 196, 224, 252, 307, 335, 364, 392, 476, 419, 448, 532, 560, 587, 616, 644, 672, 700, 714
Arachnoid Membrane, Ganglionic Character of, 52
Arnott, Dr. J., On Indigestion: its Pathology; and Treatment by the Local Application of Uniform and Continuous Heat and Moisture,—(Review,) 128
Arsenic, Detection of, 51
..... Employment of, 459
..... Medicinal Action of, Inquiry into, 268
..... Paralysis produced by, 305, 459
..... Poisoning by 78, 347, 391, 418, 445
Arsenical Poisoning and Cholera, Diagnosis of, 669
Arsenite of Copper, Poisoning by, 374
Artery Carotid, Aneurism of, 579
..... Right Subclavian, Note on One of the Anomalies of, with Absence of the Recurrent Nerves of the Right Side, 584
Ascites, Intestinal Irritation a Cause of, 160
Asphyxia, Treatment of, 332
Asthenia, Death by, 215
Asthma, Chloroform in, 54
Astragalus, Compound Fracture and Dislocation of, 385

Astragalus, Dislocation of, 693
Atalectasis Pulmonum, 641
Atresia Ani, 580
Axilla, Tumour in, thought to be Carcinomatous, 400

B.

Bainbridge, F., Chloroform in Catalepsy, 205
Bakerian Lecture : Mr. Faraday's New Discovery, 711
Ball, S., An Account of the Cultivation and Manufacture of Tea in China,—(Review,) 183
Baptism of Sick Infants, 167, 195
Barham, Dr. C., Case of Permanently Slow Pulse, 431
..... On Burns, &c., in the Royal Cornwall Infirmary, 437
Barker, Dr. T. H., On Burns, &c., 76
Baron, M., Memoir on the Localization of Skin Diseases, 328, 387, 413, 441
Barrow, B., Effects of the Direct Application of Chloroform to a Decayed Tooth, 503
..... On Burns, &c., 209
Bath and Bristol Branch of the Provincial Medical and Surgical Association, 336, 405, 612, 644
Bebeerine, Sulphate of, in Strumous Ophthalmia, 568
Bell, Dr. C. W., Lectures on the Nature and Treatment of Cholera, considered with Reference to its Analogy with Congestive Agues of Quotidian Type, 645, 673, 701
Belladonna, Poisoning by, 470, 523, 531, 558, 628
Benevolent Fund, 105; Report of, 461
Benzoin, Fumes of in Aphonia, 161
Berncastle, Dr., and the Croydon Guardians, 139
..... Memorial to, 196
..... Testimonial to, 139, 223, 335, 392
Bilary Concretion, 710
Birmingham Pathological Society, 19, 47, 104, 186, 236, 298, 365, 549, 664, 710
Black, Dr. G., On Burns, &c., 78
..... Dr. J., Observations on the Pestilential Cholera of 1832-3, 29
Blackmore, Dr. E., Facts relative to Epidemic Cholera, detailed from Personal Observation of the Disease at Plymouth, in 1832, 482
Bladder, Abscess of, 187
..... Diseased, 19, 579
..... Irritable, from Tape-Worm, 190
..... Pessary introduced into, 214
..... Rupture of, from Injury; Recovery, 110
Blood, Arterial and Venous, Difference between, 218
..... Composition of, 241; in Scurvy, 272
..... Necessity of Facilitating the Descent of the Diaphragm in Diseases which impede Aeration of, 214
..... New Method of Detecting Sugar in, 669
..... Spots of, Method of Recognizing, 416
Bone, Nerves of, 23
..... Pains in, 583
..... Syphilitic and Scrofulous Affections of, Diagnosis between, 415
Boult, E., Observations on the Employment of the Alcholic Extract of Nux Vomica, 260
Bowels, Obstruction of, 92
..... Overloaded, Effects of, 232
Bowels, Overloaded, Head Symptoms from, 215
Bowman, J. E., An Introduction to Practical Chemistry, including Analysis,—(Review,) 663
..... W., Lectures on the Parts concerned in the Operations on the Globe, and on the Structure of the Retina,—(Review,) 709
Brain, Abscess of, 487
..... Fungoid Tumour in, 413
..... Fungus Hæmatodes in, 510
..... Inflammation, limited to the Serous Membranes of the Ventricles of, and its Termination in Chronic Hydrocephalus, 300
..... On the Two Movements of, 668
..... Softening of, 355
Breast, Pendulous Tumour of, 48
Bronchitis and Death in Consequence of Two Teeth being driven down the Larynx, 707
Bronchus, Impaction of a Tooth in, 163
..... Rupture of, 579
Bruit de Diable, Cause of, 189
Bryan, J. M., Case of Poisoning with Arsenite of Copper; with Remarks, 374
Buchu in Dropsy, 120
Budd, H. W., Two Cases of Delivery under the Influence of Chloroform, 62
Bullen, G., Case of Lithotomy, the Calculus weighing Seven Ounces, 150
Bulley, F. A., On Burns, &c., 155, 351
Burial Clubs, 587
Burn, Cicatrix from, 593
Burns, Application in, 163
..... Division of the Cicatrices in, 421
..... Treatment of, by Ice, 219, 301
..... and Scalds, Inquiry into the Treatment of, 16, 42, 73, 100, 129, 154, 184, 209, 269, 295, 324, 349, 382, 403, 435
..... by Fire, Protection from, 472
Busk, W., Foreign Body impacted in the Uterus, 347

C.

Cæsarean Section, 414
Calculi, 592, 694
..... Encysted Vesical, 386
Calculus, Mulberry, 47, 385
..... of Kidney, 412
..... Urethro-Perineal, 109
Camphor, New Vehicle for holding in Solution, 80
Cancer of the Tongue, 689
..... of the Upper Lip in the Female, 530
..... of the Uterus, simulated by the Irritation of a Sponge, 162
Cancerous Tumour from the Clitoris, 300
Cancrum Oris, 415
Carcinomatous Affections of the Spine, 275
Carlyon, Dr. C., On Nitre in Purpura Hæmorrhagica, 682
Carotid Artery, Aneurism of, 579
Carotids, Ligature of both Primitive, 530
Cartilages, Loose, 501,
Cases from Private Practice, 38, 63, 93, 262, 289, 378, 516, 544, 569
Castle, Dr. H. T., Case of Poisoning by Fowler's Solution: Abortion : Mortal Fainting, 347

Castle, Dr. H. T., Reply to Mr. Hunt on the Minimum Fatal Dose of Arsenic, 418
Catalepsy, Chloroform in, 205
Catheter, On the Introduction of, 493
Cauterization of Adherent Omentum in Strangulated Hernia, 530
Cautery, Actual, in Neuralgia, 54
Cerebellum, Clot in, 237
..... Partial Softening of, 236
Cerebral Inflammation, Treatment of, 53
..... Softening, 561
Chambers, Dr., Retirement of, 364
Chloroform, 51
..... Administration of, Request for Information on, 223
..... Death from, 83, 582
..... Direct Application of to a Decayed Tooth, 503
..... Extraction of a Needle from a Child under the Influence of, 320
..... in Amputation, 61
..... in Asthma, 54
..... in Catalepsy, 205
..... in Cholera, 586, 614, 615
..... in Cholera Infantum, 627
..... in Chorea, 414
..... in Diarrhœa, 655
..... in Dislocation, 232, 656
..... in Dysentery, 627
..... in Infantile Convulsions, 305
..... in Parturition, 62, 333
..... in Puerperal Convulsions, 192, 333
..... in Tetanus, 204, 300, 332
..... in Tooth-ache, 531
..... Local Effects of, 353, 365, 459
..... Necessity of Employing in a state of Purity, 656
..... New Method of Preparing, 445
..... Use of, 28
..... and Æther, Comparative Effects of, 241, 272
Cholera, Epidemic, 28, 252, 307, 335, 364, 419, 472, 504, 560, 587, 613, 616
..... Chloroform in, 586, 614, 615
..... considered with Reference to its Analogy with Congestive Agues of Quotidian Type, 645, 673, 701
..... Directions of the College of Physicians of London, relative to, 638
..... Inquiry into the Etiology of, 694
..... Observations on, 594, 681
..... Petroleum in, 390, 446, 471, 503
..... Phosphate of Soda in, 503
..... Report on, 617
..... Speedy Interment of Persons dying from, 532
..... of 1832-3, Observations on, 29
..... Epidemic, Facts relative to, at Plymouth, in 1832, 482
..... and Arsenical Poisoning, Diagnosis of, 669
..... Infantum, Chloroform in, 672
Chordæ Tendineæ, Rupture of, 304
Chorea, Chloroform in, 414
..... Clinical Lecture on, 169
..... Connection of, with Rheumatism, 24
..... and Rheumatic Endocarditis, 541
Cicatrix from a Burn, 593
Circulating System, Diseases of, 589
Cirrhosis of the Liver, 590, 666
Clavicle, Fracture of, 54, 55, 547, 583
..... Luxation of, 54
Clinical Medicine and Surgery in the Continental Hospitals, 214, 314, 356, 499, 552, 580
..... Notes from Private Practice, 206, 238, 263
Clitoris, Cancerous Tumour from, 300,
Clough, Mr., On Burns, &c., 158
Club-Foot, Gutta Percha in, 529
Cold Applications in Rheumatism, 25
Cole, H., Burns &c., treated in the Worcester Infirmary, 325

MEMOIR ON TURNING, AS AN ALTERNATIVE FOR CRANIOTOMY AND THE LONG FORCEPS, IN DEFORMITY OF THE BRIM OF THE PELVIS, &c. &c.*

By J. Y. Simpson, M.D., F.R.S.E.,
Professor of Midwifery in the University of Edinburgh, &c., &c,

Part II.

Sect. III.—Theory or Principles of the Proposed Practice.

The form of the infant at birth, has often and justly been compared to that of a cone; the feet serving as the apex, and the arch or biparietal diameter of the head forming the basis of the cone, and there being a gradual tapering and increase of size from the former to the latter point. Consequently, when in cephalic presentations, the head or broad end of the cone once dilates and passes a given point, the narrow remainder of the cone, viz., the trunk and extremities, afterwards pass it without impediment. In fact, both in cranial and in footling presentations,—even in instances of contracted pelvis,—the transit of the body is usually attended with no special difficulty or delay. The obstruction is referrible to the child's head alone; and hence the necessity of accurately studying the obstetric configuration and relations of the fœtal head, in order to be able to overcome the obstruction offered by this part.

Now, besides that the whole infant is, as I have just stated, of a conical figure, the head taken alone, presents more imperfectly the same configuration; for the basis of the skull is considerably narrower than the arch; or, in other words, its bimastoid diameter, (*b b, fig.* 1,) is less than its biparietal diameter, (*a a,*) so that the cranium increases gradually in breadth and size, like the whole body, from below upwards.

The biparietal diameter of the head or vertex is, in this way, the *basis* both of the cone of the whole body and of the cone of the head taken singly.

Fig. I.—Vertical section of a fœtal skull, shewing its conical form.

To understand thoroughly, however, the subject of our present enquiries, it is necessary to have some more precise and definite ideas of the degree of tapering of the cranium from its broad arch to its narrow basis; or, in other words, it is requisite to fix more accurately the degrees of difference between the biparietal and bimastoid diameters of the head. With this view, I some months ago, made upon the heads of several new-born infants a variety of measurements relative to these two points. I arrived at nearly the same conclusions as those which I afterwards found Mr. Tomlinson had previously obtained, when admeasuring the fœtal head for the purpose of assisting Dr. Hull in his enquiries as to the smallest dimensions the skull could be possibly reduced to, by the operation of craniotomy. And to prevent all cavil I will here take Mr. Tomlinson's measurements as standard and correct, and the more valuable on this account, that they were made and published without any view to such a question as the present.

Mr. Tomlinson gives among other measurements of the head, the breadths of the biparietal and bimastoid diameters in six infants at birth. I shall throw them into a tabular form, and add a column, shewing the difference between these two diameters in each case.

* Continued from page 676 of last volume.

TABLE I.

Measurements of the Biparietal and Bimastoid Diameters of the heads of six Infants at Birth.

Number of Case.	Biparietal Diameters.		Bimastoid Diameters.		Difference between the two.	
	In.	8ths.	In.	8ths.	In.	8ths.
I.	3	— 4	2	— 7	—	5
II.	3	— 6	3	— 2	—	4
III.(a twin)	3	— 1	2	— 6	—	3
IV.	3	— 2	2	— 6	—	4
V.	3	— 3	2	— 6	—	5
VI.	3	— 4	2	— 6	—	6

We thus find a difference between the bimastoid and biparietal diameters of the head, varying from three-eighths to six-eighths of an inch; or from four and a half to nine lines. Or, if we exclude, (as in fact should properly be done,) the third case, as being a twin infant, and consequently having the head and body smaller and less remarkable than in a single and full-sized child,—then we have in the remainder a difference between the biparietal and bimastoid diameters, varying from six to nine lines; that is, from four to six-eighths of an inch; or, in other words, *from half an inch to three quarters of an inch.** And in artificially extracting an infant through a narrow pelvis as a footling instead of a head presentation, we may gain, I believe, when necessary, this great difference between the size of the body to be extracted, by varying the method of the extraction itself. For it must be further held in view that at its base, (or bimastoid diameter,) the cranium of the infant is so strong, and its bones so firmly and densly united as to render it quite incompressible. On the other hand, in its arch (or biparietal diameter,) the cranium at birth is, in general, so thin, and its bones so loosely and imperfectly united, as to permit of the head being much flattened and compressed, or even depressed and indented at some point, without necessarily destroying life.

Now, when the brim of the pelvis is morbidly contracted at one part,—let us imagine, for instance, its conjugate diameter to measure only three inches instead of four,—then the child, upon being forced down upon it as a head-presentation, meets with difficulties which, probably, no uterine effort could possibly surmount. A round body, the diameter of which is some lines *above* three inches, is attempted to be pushed through an opening measuring *only* three inches. But, turn the child, extract it footling, and let the head pass through the contracted brim by engaging in it, first the base or bimastoid diameter of the cranium, and the difficulty may possibly be overcome; for then we have the head entering the contracted brim of three inches as a body *less* in its diameter than three inches, and capable of having its broader upper portion flattened, and reduced to the size necessary for its complete transit, by the force which we can apply to the already protruded body of the infant, producing the requisite degree of lateral compression of the cranium against the opposed sides of the contracted pelvic brim.

Or, let us take another and perhaps simpler view of the subject. Suppose, in want of a better wood-cut, we take the letter **A** as a round cone simulating the figure of the infant, the apex of the letter corresponding to the feet of the infant, the base of it corresponding to the biparietal diameter of the head, and the cross-bar of the letter representing the incompressible floor or basis of the skull, and the two divergent feet of it representing the elastic and compressible arch of the cranium. Now, if we desired to pass this round cone **A** through an oblong aperture **O**, the diameter of which was somewhat *less* than the diameter of the basis of the cone, would we succeed best by pushing it through the oval opening with its basis foremost, or by dragging it through it with its apex foremost? If we extract the cone through the aperture by bringing its narrow end foremost,—or, in other words, if we bring the child by the feet instead of the head,—then two objects are gained; for, first, we have the power of using any justifiable degree of force that may be required, by the command we thus obtain of the protruded and narrow end of the cone; and, secondly, the elastic sides of the base of the cone situated above the cross-bar,—or, in other words, the sides of the cranium itself above its basis,—will yield and become compressed together to such an extent as to enable the collapsed body to pass through the supposed opening. If, on the other hand, we attempt to make the broad basis of the cone, (or the vertex of the head,) to pass first through an aperture less than its own diameters, then we are apt, the more we press, to increase rather than diminish the difficulty attendant upon its transit; for the more force we apply we are liable to render that part which is already too broad still broader, by flattening it against the sides of the aperture, and making its limbs or parietes at one point or another diverge and widen, instead of converge and contract. It is true that if we can insinuate *obliquely* or otherwise, the basis of the compressible cone (or the arch of the head,) into the contracted aperture, so as to get *its* sides compressed between the sides of the opening, and consequently its biparietal diameter lessened by the force with which the body of the cone is pushed downwards, a similar object would be gained, but in a more uncertain and imperfect degree. Besides, there is always in this way the chance of making the two sides of the cranial arch, (2 2, *fig.* 2,)

* "From the one parietal protuberance to the other, a transverse line measures from three inches and a quarter, (3¼.) to three inches and a half, (3½.) From one mastoid process to the other along the base is about two inches, (2.) From the one temple to the other is two inches and a half, (2½.)"—*Dr. Burns' Principles of Midwifery*, 10th Edition, p. 25.

spur out, and diverge lower down at *their* basis, in proportion to the amount of force applied to the upper surface of the arch itself, (*c c, fig.* 2,) so that while we contract the sides of the arch above by the kind of pressure applied to it, the direction of that pressure may

Fig. II.—Illustrating the effect of pressure upon the top of the arch of the fœtal cranium, as happens when the head presents.

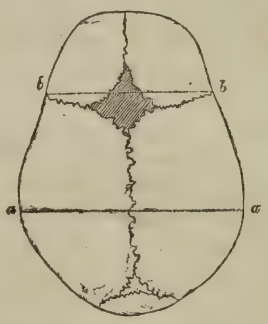
Description of Fig. II.—The dotted line *c b b c* is the vertical section of a normal fœtal skull, as seen in *Fig. I.* The outline 1, 2, 2, shews the disadvantageous alteration in form produced by the presentation of the head to a contracted pelvis.

possibly widen and open the limbs of the arch below, and so far increase, for the time being, the difficulty accompanying the transit of that part.

But this transverse or lateral form of flattening and compression of the cranium is very far indeed from being always obtained when the vertex is allowed to present at the brim of a distorted pelvis; for frequently the whole, or the greater mass at least, of the head remains obstinately above the brim, despite the action of the propelling efforts upon it of labour-pains, both dangerous in the amount of their duration, and dangerous in the amount of their force. By bringing, however, the *apex* of our cone, or the narrow diameters of the cranium foremost, we not only improve and simplify the mechanism of the labour by so far converting the entrance and passage of the child's head into the contracted pelvic brim, from a matter of comparative chance into a matter of comparative certainty; but further, we effect, thus, in the course of minutes by turning, what it might require the course of hours or days to accomplish, provided the transit of the fœtal head were left as a head-presentation to nature alone, or to nature assisted at last artificially by the long forceps or crotchet.

But other advantages are obtained by turning, as compared with embryulcio and the long forceps, in the class of cases which we are considering. We not only bring the tapering or cone-shaped fœtal head through the distorted brim, by making its narrow extremity enter first into the contracted aperture, and *afterwards* using the sides of that aperture to compress the elastic parietes of the broader and higher part of the cranium, but in some cases we in this way, I believe, eschew altogether engaging the broadest part of the head (*a a, fig.* 3,) in the narrowest part of the contracted pelvic opening,—a circumstance and adjustment that, in a head-presentation, would be otherwise quite unavoidable. For besides being found of a conical form when looked at vertically, the infantile head shews the same configuration also when viewed antero-posteriorly. The accompanying outline, for instance, of the fœtal head, as seen from above, is an exact copy of that given in

Fig. III.—Outline of the fœtal head as seen from above.—(From Chailly.)

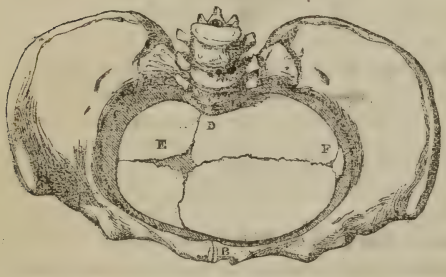


Chailly's late work on Midwifery, and shews that while the head is very broad behind in its biparietal diameter, (*a a, fig.* 3,) it gradually tapers and diminishes in breadth as we proceed forward to its bitemporal and bifrontal, (*b b, fig.* 3,) diameters; and its bitemporal diameter is in general fully half an inch less than its biparietal. But, in the mechanism of head cases, the neck, as is well known, becomes early flexed in the labour, so that the chin is brought towards the top of the sternum, and the vertex or upper and back portion of the head first becomes pushed downwards into the pelvic aperture, and thus constitutes the presenting part,—in other words, the broadest part of the cone of the whole child, because the broadest part of the head, or its biparietal diameter, is thus naturally first driven downwards into the pelvic cavity, and is first directed against the contracted brim. The same head, when extracted as a footling presentation through the same distorted pelvis, will in some instances entirely escape, having this, its broadest part, placed and engaged in the narrowest part of the pelvic aperture; for, as the extremities and the body of the child are gradually extracted in the operation of turning, the head, in ultimately adapting itself to the shape of the pelvis, comes to have its bitemporal, and not its biparietal, diameter implicated in the narrowest or conjugate diameter, the parietal protuberances passing into the wider lateral space opposite the sacro-iliac synchondrosis. That such is the fact, the position of the mark or indentation upon the skull, produced by compression against the protruding promontory of the sacrum in Case I, and in other instances which I shall afterwards quote, amply proves.* The injury and depression of

* See, for example, the figures of indented fœtal skulls given by Professor Sandifort, in pl. xxxiv. of Vol. II. of his *Museum Anatomicum*.

the cranium, if any, seems always situated before the ear, and consequently much before the parietal protuberance; or, in other words, it is, as I have said, in the temporal region. The anterior edge of the parietal bone, or the anterior edge of it and the corresponding posterior edge of the frontal, are generally the osseous points that are depressed and indented, as represented in the accompanying diagram.

Fig. IV.—The form in which the bones of the fœtal cranium are compressed in passing through a contracted brim.

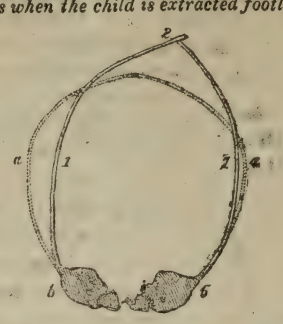


Description of Fig. IV.—A. Promontory of sacrum. B. Symphisis pubis. C. Unoccupied space between the ilium and forehead of the child. D. Depression in child's head corresponding to the promontory of the sacrum. E. Anterior fontanelle. F. Posterior fontanelle.

Now, the child's head narrows greatly from behind forwards, from the occiput towards the forehead as seen in *fig.* 3; and in the temporal region its diameter is generally from three to five-eighths of an inch, or from four and a half to seven and a half lines *less* than between the two parietal protuberances.* Hence it is evident that a great gain is affected by the head passing through the narrowest part of the brim, with a diameter at least several lines less than it otherwise would offer, provided it happened that the vertex of the head had been kept and retained as the presenting part.

In order that the full-sized fœtal head may pass through a contracted pelvic brim we require to have the head flattened laterally, and its sides at its anterior parietal or temporal region collapsed and compressed. The outline *a b b a, fig.* 5, is the outline of the vertical section of the infants skull that I have already given in *fig.* 1. The line 1, 2, 1, *fig.* 5, marks what we may presume, for the sake of illustration, to be the shape and degree of compression to which the head would require to be reduced in order to pass the contracted pelvic aperture.

Fig. V.—Illustrating the effect of lateral compression upon the sides of the arch of the fœtal cranium, as happens when the child is extracted footling.



Description of Fig. V.—The dotted line, *a b b a*, is the vertical section of a normal fœtal skull, as seen in *fig.* 1. The outline 1, 2, 1, shews the advantageous alteration in form produced upon the fœtal cranium by extracting the child footling through a contracted pelvis.

Would this necessary degree of compression be effected more easily and by less amount of force if the head were drawn through the narrow pelvis as a footling presentation, than if it were driven into it as a cephalic presentation? I certainly believe that less power would be required to produce the same degree of lateral compression and collapse in the cranial arch, provided the compressing force were applied, (as in cases is which the child is extracted footling,) directly to the two sides or lateral surfaces (1, 1, *fig.* 5,) of the arch itself, than under the alternative condition supposed. For if the child descended into the pelvic brim as a head presentation, the uterine contractions would drive it against the narrow points of the pelvic brim, so that the reacting compressing power of these points would be applied either to the two upper surfaces of the arch, (*c c, fig.* 2,) or partly to one of them (c), and partly to one of its opposite lateral surfaces, (*a a, fig.* 5.) In such circumstances the compressing powers would be acting much more indirectly and far more at a disadvantage in effecting the required compression, than if they were applied, as in extracting the child footling, directly and immediately to the sides themselves, (*a a, fig.* 5,) that are to be compressed.

"Does the head, (asks Dr. Radford,) elongate more readily upwards than downwards? If only (he answers,) the same degree of extractile force is used, it does not." But what I have stated shews that the same degree of extractile force will produce the desired effect more easily, and as we shall afterwards see, more safely also, when the child passes with the pelvis, than when it passes with the head first. And this I believe, affords us another advantage in the mechanism of footling as compared with cephalic presentations in instances of diminished pelvic brim. We are enabled to produce by it the same amount of compression of the fœtal head by a less expenditure of compressing force, for we apply it to the lateral surfaces or piers of the cranial arch, (*a a, fig.* 5,) and not to its pedentures

* See preceding note from *Dr. Burn's Midwifery.* Chailly gives the biparietal diameter as three inches and a quarter ($3\frac{1}{4}$) to three inches and a half, ($3\frac{1}{2}$); and the bi-temporal diameter as two inches and a half ($2\frac{1}{2}$) to three inches, (3.) —See his *Treatise on Midwifery*, 1844, translated by Dr. Bedford, p. 62.

or upper surfaces, (*c c, fig.* 2.) We effect a saving of force by the *direction* in which we apply the force.

I am well aware both that it is exceedingly difficult to state accurately and intelligibly the opinions one may happen to entertain on such a subject as we have been discussing in the present section, and that I am far from having succeeded in making the demonstration so simple as I could wish. It may assist, however, our comprehension of the matter if, before concluding it, we try to re-capitulate and sum up the advantages which, in regard to the mechanism of labour, are, in the contracted states of the pelvic brim, obtained by the child passing as a footling instead of as a cephalic presentation. These advantages, as far as I have hitherto attempted to trace them in the preceding remarks, (for we shall trace out more of them afterwards,) amount to the following:—

1. The fœtal cranium is of a conical form, enlarging from below upwards, and when the child passes as a footling presentation, the lower and narrower part of the cone-shaped head is generally quite small enough to enter and engage in the contracted pelvic brim.

2. The hold which we have of the protruded body of the child, after its extremities and trunk are born, gives us the power of employing so much extractive force and traction at the engaged fœtal head, as to make the elastic sides of the upper and broader portion of the cone, (viz., the biparietal diameter of the cranium,) become compressed, and, if necessary, indented, between the opposite parts of the contracted pelvic brim, to such a degree as to allow the transit of the entire volume of the head.

3. The head in being dragged downwards into the distorted pelvis, generally arranges itself, or may be artificially adjusted, so that its narrow bi-temporal, instead of its broad bi-parietal, diameter, becomes engaged in the most contracted diameter of the pelvic brim.

4. The arch of the cranium or head is more readily compressed to the flattened form and size required for its passage through a contracted brim, by having the compressing power applied, as in footling presentations and extraction, directly to its sides or lateral surfaces, than by having it applied, as in cephalic presentations, partly to the lateral and partly to the upper surfaces of the arch.

Lastly, I may add, as a result of the whole mechanism, that the *duration* of the efforts and sufferings of the mother is greatly abridged by turning, when used as an alternative for craniotomy and the long forceps, and that thereby her chances of recovery and safety are increased. But as this is in itself a matter of the highest moment, in reference to the whole question of the proposed practice, we shall devote a special section to the consideration of it.

(To be continued.)

OBSCURE CASE OF SUDDEN DEATH: ENLARGED THYMUS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I venture to send you the following case for publication in the *Provincial Journal*, being quite unable to satisfy myself as to its nature, and hoping that some one of your readers may do me the favour to assist in enlightening me,

I am, Sir,
Your obedient servant,
T. OGIER WARD, M.D., OXON.

Kensington, Dec. 13, 1847.

September 28th, 1847. A. B——, aged seventeen months, a male child, of delicate constitution, was taken out by his mother into Kensington when the air was cold, and scarlatina was prevalent. On her return she laid him down to sleep, from which he awoke crying and shivering, and would not be pacified until she took him down stairs into the shop, (a blacksmith's,) where his father was at work. After this he ate a good dinner of apple-pudding, but as he became feverish, and seemed to have a sore throat, she procured a powder from the druggist's, and gave it to him at night. It opened his bowels, but the fever continuing the next day and the day following, she sent to me in the evening. I found the child hot and a little flushed, and restless, and I was told he had had frequent startings of the body and limbs, but I observed none, nor had he any cough or difficulty of breathing, nor any head symptoms; his bowels had not been opened for two days, and though his mother said he was teething, she was averse to my lancing his gums then, as he was quieter than he had been for some hours. I could not detect any external enlargement of the tonsils, and I prescribed a warm bath, and a saline aperient mixture.

The next day, October 1st, he was so much better, and his bowels had been so well relieved by the mixture, that I ordered it to be continued at longer intervals, and lanced one of his eye-teeth that seemed to be most prominent under the gum. He was much better when I saw him the following day, about eleven a.m., and I ordered him a saline mixture, with nitric æther, (more as a placebo than because he really seemed in want of any medicine,) to remove the remains of the fever.

At one p.m., at his parents' dinner, he took a bit of finger-biscuit, which his father dipped in his beer for him, his appetite having been very bad previously. About half-past three p.m. he grew worse, and his breathing became difficult, and at half-past six p.m. I was sent for, and found him with a rapid pulse; a warm, damp, but not livid, skin; rapid breathing, interrupted by occasional gasps, and making a weak moaning cry every four or five breaths. The breathing seemed to be performed almost entirely by the diaphragm, and on applying my ear to the chest, there was no vesicular murmur, but harsh bronchial respiration. Percussion also was not clear, as usual, indicating the entrance of very little air into the

chest. There was no enlargement of the tonsils, though his mother still persisted in saying his throat was sore; nor any cough, nor more difficulty in taking the breast, than is usual in the chest affections of infants. The eyes were natural. I observed no spasms, nor any retraction of the thumbs into the palm of the hand, nor any indication of cerebral disturbance. I ordered a mustard poultice to the throat as a preliminary to a blister, and then gave an emetic of ipecacuanha, which was swallowed without difficulty, but brought nothing back with it when it operated, which it did in about half an hour. The mustard caused no redness of skin, nor the blister any irritation apparent during life. I also used a hot bath, and as the child became colder, I put him into bed to his mother. In fact the child seemed to be struck with death, similar to what I have observed in the asphyxia of new-born infants, or in cases of half-drowned children, the breathing, the moaning, and occasional gasping, being precisely the same, but in this case, with no lividity till just at the close. Finding the above remedies of no use, I gave brandy and beef tea, which were swallowed with ease, and apparently relished, and seemed to revive the child for a moment, but only for him to fall back into a weaker state. Having exhausted every means of treatment I thought of use, I sent for Mr. Merriman, who very kindly came to my assistance, but by this time nothing but stimulants had any effect, and shortly afterwards the little patient was unable to take even these, and died at half-past one a.m., without a struggle, and with no tracheal rattles till just at the last.

Post-mortem examination sixty hours after death. With great difficulty I obtained permission to examine the chest alone. Body pale, slightly livid on its under surface; skin of throat horny where the blister had been applied; no swelling of tonsils; larynx, trachea, and bronchi pale, and unobstructed by mucus; lower lobes of lungs condensed and congested, the venous black blood flowing out unmixed with froth when they were incised; upper lobes also condensed, scarcely crepitant, and congested at their back part; the whole lungs hardly floated with a third of their bulk above the surface of the water; no fluid in the pleura, and but little in the pericardium; right cavities of heart gorged with black fluid blood; walls, cavities, and valves, normal. Decomposition had scarcely begun, though the body was in a warm room, and the weather also was warm. The liver was dark with congestion, but there was no general venous congestion of the internal organs, as in cases of asphyxia, though a good deal of black fluid blood flowed from the jugulars when they were divided. The thymus gland was about four inches long, one and a half or two inches broad, and about three quarters of an inch thick; but except being irregularly lobulated at its upper part, presented no appearance of disease, unless its pink colour were a sign of inflammation.

My first impression upon seeing this patient was that he was affected with scarlatina in the first stage, before the appearance of the eruption, and this opinion was not changed by anything that occurred until my last visit, for, according to the mother's account the child complained frequently of his throat, or at least, made her believe that he did, as he could not speak, being only seventeen months old. I therefore carefully examined him at each visit to see if the eruption had come out, and if the tonsils were enlarged, but I could perceive nothing of the kind.

My next idea, when I found him gasping and hoarsely moaning, was, that the preliminary fever had been that of croup, and that the formation of a membranous exudation in the trachea had just commenced.

Again, I thought it might be spasm of the glottis; but as the disease advanced, and the dyspnœa increased, all that I could ascertain was that the child was dying from inability to respire freely; though I was quite unable to decide whether the respiratory nerves or muscles were in fault, or whether there was any mechanical obstacle in the respiration,

Let us now examine which, or whether any of these ideas were correct:—First, the extreme prevalence of scarlatina in Kensington at the time, and the suddenness of the attack, together with the complaint the child is said to have made of his throat, though the tonsils were not swelled so as to be felt outwardly, support the notion that the case was one of scarlatina; but as the eruption never showed itself in the slightest degree, and there appeared to be no change in the solids or fluids of the body that could be referred to intense zymotic influence,—in other words, no symptoms of malignancy,—I think we must lay aside this idea; at least, my own experience affords me no instance of death from an infectious disease, or from its retrocession, or want of development, without some evidence of its effects, local or general. Still, I would submit for consideration, whether the poisonous element might not have been in the system, and that it was the cause of death, as in asiatic cholera we observe infants, and even adults, turn blue and cold, and die, with every outward appearance of the disease, except the active symptoms of vomiting and purging. In the only two cases of undeveloped and retrocedent eruption (measles,) that I have examined after death, in the one, (the retrocedent,) the blood was evidently decomposed, every organ, as well as the skin, being marked with purpuric spots, and the thymus gland much enlarged; in the other, (the undeveloped,) the child died asphyxiated, but in a more lingering manner, and the blood was partially coagulated; there was congestion of the liver and thoracic viscera, and the thymus was so folded upon itself, as, with the enlarged bronchial glands, to form a mass of considerable thickness in front of the trachea at its bifurcation. In the present case the blood was black, and fluid, as might have been expected from the kind of death, but the various organs, except the lower lobes of the lungs, the right side of the heart, and the liver, were free from anything like congestion or effusion of blood.

Again, if the complaint had been croup, there would have been earlier proof of its local action, either in the cough, or dyspnœa, or pain in the throat of a more decided character than was present in this case previously to the close; besides that, it would have left

some *post-mortem* appearances of its effects; whereas, the larynx, trachea, and bronchi were pale and free from all obstruction.

With regard to the third idea that presented itself,—viz., that the child laboured under an attack of spasm of the glottis, even if it were so, it would not explain the preliminary affection of four days' duration, which exhibits no one symptom of this disease, if we except the sudden awakening from sleep at the onset; and this symptom can have but little weight in establishing the diagnosis of a disease, for every medical man who has a family, or has been much in the nursery, must be well aware how frequently children awake suddenly, and with a cry, without any disorder following; in fact many children never awake without giving this evidence of their having done so.

But it may be said that the antecedent febrile state belonged to scarlatina, or some other disease, and that spasm of the glottis was excited by it, and caused the fatal result. To this I would reply, that the spasm, being a sudden disease, more or less complete, of the glottis, could not admit of alternations and remissions occurring every three or four inspirations, and causing no more proof of suffocation for nine hours than an occasional gasp, without any corresponding expression of distress in the countenance till the tracheal rattle supervened. There were neither struggles for breath, crowing inspiration, nor any signs of suspended respiration; the air evidently entered the larynx, though it did not penetrate completely into the lungs, neither was there any mucus in the trachea, (so common an exciting cause of spasm in the glottis, in those who are subject to it,) nor any difficulty of swallowing, though there was of sucking. Not satisfied, however, with my own experience in this complaint, I have carefully examined the history of every case of spasm of the glottis that I have been able to meet with, without finding a single instance analogous to this in its uninterrupted course. There are indeed some cases recently published under this title, by Dr. Wardell and others, in the *Provincial Journal*, the claims of which, however, to this name I purpose to discuss hereafter, as I think them by no means entitled to this appellation.* But, with the exception of these cases, every writer concurs in describing the symptoms of the complaint now generally known under this name, as equally sudden in their access and remission, whether they terminate in the death or recovery of the patient.

But to return to our immediate subject—the cause of death in this case. Though I could not trace the affection back to its source, yet it was evident,—first, that the respiratory organs were in fault. The chest did not properly expand to admit the air, and the lungs seemed (by their state after death,) not to have filled the cavity of the chest, if such a thing were possible; yet the diaphragm contracted freely, and hence there could have been no defect in *its* nervous supply whatever might have been the case with regard to the respiratory muscles that raise and expand the ribs. These could not have had their proper energy, otherwise the air must have penetrated into the lungs; for if the trachea only were obstructed, there would have been a stronger evidence of such an obstacle than was exhibited by the symptoms. The same reasoning will suffice to prove that the laryngeal nerves were not in fault. From the nerves we must refer backwards to the medulla oblongata and the brain; but although I was not permitted to examine the head, yet there was such a perfect absence of any indication of head affection throughout the course of the disease, neither sickness, strabismus, contraction, nor dilatation of the pupils, clenched hands, convulsions, stertorous breathing,—nothing in short, except one rigor and occasional starting at the outset of the attack, that I can hardly persuade myself that the brain was in fault, as the source of the disease. Secondly, if neither the medulla nor the respiratory nerves of the larynx nor of the diaphragm were paralysed, and yet the ribs did not move, we must look to the source of this motivity, if not for the cause of death, at least for the reason of the want of action in the intercostal muscles, &c. Now, both anatomy and pathology informs us that they are supplied from the brain through the medium of the spinal nerves, though authors are not agreed upon the exact source of the nervous influence. Analogy, however, from the similarity of the symptoms in this case to those of drowning and asphyxia, and the moribund state, support the idea that a general depression of the nervous system was the cause that the deep-drawn inspirations in this case, were almost confined to the action of the diaphragm; and the beneficial effect of the stimulant remedies serve to confirm this view, and to lead us to consider the struggle of the last hours the result of depression induced by previous disease.

From a careful consideration of the cases of spasm of the glottis that have been published, I have been led to divide them into two classes, the acute and chronic, the former being fatal at the first attack, and the second recurring frequently, and being either fatal or curable. The latter class I should refer to the pressure and irritation of the respiratory apparatus, by tumours of various kinds, both in infants and adults; and the former as being the effect of pure spasm, excited by some transient cause that leaves no traces after death. It is remarkable that spasm of the glottis is a disease of infancy, when the thymus is still unabsorbed, and while there exists the greatest tendency to the formation of glandular and scrofulous swellings; and though we often have similar swellings in the adult without the coincidence of spasm, yet this difference in the results may be explained by the greater mobility of the nervous system of the infant inducing spasmodic action from very slight causes of irritation.

I have reserved till last, the consideration of the effect the enlarged thymus might have had in the production of the complaint, because in all the cases of this condition of the gland that I have been able to meet with, the symptoms partook of the sudden character of spasm of the glottis,—so much so, that the reviewer of Dr.

* Since I wrote the foregoing remarks, a case has occurred to me fully bearing them out, but which I must reserve for a future communication.

Hirsch's work on this subject, in Vol. 2 of the *British and Foreign Medical Review*, scarcely notices the account of the German author, except to state that it is not his discovery, but that it belongs to Mr. Hood, of Kilmarnock, (who published several cases of diseased thymus, in Vol. 3 of the *Edinburgh Medical Journal*, under the head of "Cases of Sudden Death,") and he refers the symptoms of all the cases observed both by the German and British authors, to spasm of the glottis or laryngismus stridulus. In the only other case I have witnessed, where the thymus was enlarged, the death occurred rather suddenly and unexpectedly, apparently from the retrocession of measles, but as I was not present, I cannot say what symptoms were exhibited at the close. Still it is worth notice, that in the present case also the early symptoms, combined with the extreme prevalence of the epidemic, led me to refer the complaint to undeveloped scarlatina. Hence I have some diffidence in proposing to account for the symptoms of the present case, by the results of a dissection confined to the respiratory organs, particularly as similar but more extensive morbid appearances have not been attended with exactly similar symptoms; though this perhaps might arise from the less amount of disease in the thymus in this case, exciting symptoms of a less urgent character than in the published cases. It is, however, not impropable that the pain in the throat and other symptoms, might have been occasioned by a pure inflammation of the thymus, and that this organ being swelled, so as to press upon the trachea and the laryngeal nerves, might interfere with the functions of respiration to such a degree as to produce a slowly increasing asphyxia, in a child which had before been the subject of a pneumonic attack, and was far from being strong and hearty.

In conclusion, as my object in publishing this case is to gain, rather than to impart, information as to the nature of the disease, I would ask any of the members of the Association, who have examined fatal cases of retrocedent erruptive disease in youug children, what were the lesions found after death?—and what was the condition of the thymus?

SHORT NOTES OF THE OPINIONS AND PRACTICE OF THE LATE JOHN PEARSON, ESQ., F.R.S., ON SYPHILITIC DISEASE.*

By W. S. Oke, M.D., Physician to the Royal South Hants Infirmary.

Primary Effects of the Syphilitic Poison on the Absorbent System.—The venereal virus having eroded some part of the surface to which it has been applied, and being absorbed, the glands of the groin and of the pubic region become contaminated. If applied to the nipple, the glands of the axilla may be affected and enlarge, though not so frequently. Syphilitic sores on the lips or tongue seldom affect the submaxillary glands.

[This would appear somewhat singular, but the assertion is borne out by what we observe in cancerous diseases of the lips, in which the submaxillary glands are by no means commonly contaminated.]

The tonsil glands are not primarily affected, as some imagine them to be, and for this reason, because they are mucus glands, and, therefore, can only be contaminated through the medium of the constitution. Absorption may take place from the surface of the urethra, and the inguinal glands become enlarged and suppurate; but this action is not to be considered as venereal, except there be urethral chancre.

It would sometimes appear that the poison is absorbed into the glandular system, from a surface not having any erosion; but this must be taken as a very rare occurrence, indeed it is a question whether there must not have been some slight abrasion which was not perceived. It is to be doubted whether adventitious matter can be absorbed in an unchanged state, and carried in that state to an absorbent gland.

Mercury fails to reduce enlarged inguinal glands, which are not venereal; on the contrary, it appears to exasperate the complaint. When the poison is taken up from a true syphilitic sore, it not unfrequently produces inflammation and enlargement of the absorbent vessel that conveys it; and a red line can be sometimes perceived, feeling like a knotted cord, and leading to the gland; but this result cannot be perceived or traced when absorption has taken place from an unabraded surface.

The period at which absorption takes place is uncertain, it is seldom earlier than a week, and sometimes not until five or six weeks.

When the sore discharges copiously, and when no particular application has been used to check it, a considerable time may intervene; but if it be soon healed, or be situated on a part where a scab has formed, absorption is likely to take place much sooner.

[This observation ought not to legislate against the application of the nitrate of silver in primary sores, as by this means the disease is sometimes at once got rid of.]

On Syphilitic Bubo.—When a venereal sore has been imperfectly healed, or when it has healed without the extermination of the virus, an enlargement of the glands in the groin takes place, and the constitution becomes affected; this, however, is not the usual progress of the disease, for more commonly the constitution becomes involved without the intervention of inguinal swelling.

When the virus has been carried into an absorbent gland, tenderness and enlargement are produced; but it does not follow that suppuration will take place, even though secondary symptoms shall arise. The virus, when it has once gained admission into the system, is probably never eradicated without a course of mercury; and it is probable, also, that a contaminated part can

* Continued from page 682 of last volume.

never entirely free itself from the poison by its own natural powers. When the virus has produced a morbid alteration in one or more lymphatic glands, the change is by no means uniform: it may assume the appearance of a true phlegmonous, of an indurated, or of a scrofulous enlargement; for although the cause is in either case the same,—viz., the venereal virus, yet the form in which the swelling appears will very much depend upon the constitution and the former condition of the system.

The phlegmonous bubo is that which proceeds according to the common laws of inflammation; it is usually produced from an ulcer, and is frequently excited by the use of strong applications to the sore. It is generally confined to one gland, is very tender from the beginning, soon grows red, and suppurates; and when it bursts, and forms a sore, it heals more kindly than the other two species.

The indolent bubo is seen in the groin, regio pubis, and upper part of the thigh, and is of a more stationary character. It will proceed without much pain, and there will be two or three indurated glands at the same time. The glands are occasionally soft and pulpy, but with no discolouration of the superincumbent skin. When these are met with in the female, they are situated more commonly in the groin, than in the pubic region or thigh. In this kind of bubo the structure of the gland is not always injured, but if the affection has existed a long time, and has ulcerated, the morbid granulations take on a spongy diseased state, projecting like a fungous matter from the bottom of the sore, which must be either extirpated or destroyed by caustic.

The scrofulous bubo is not easily distinguished from the indolent; perhaps the indolent often degenerates into the scrofulous bubo. It has a large diseased appearance, with the skin of a purplish-red hue, and seldom terminates by resolution.

It is not uncommon for the inguinal glands to become enlarged under a course of mercury. This is often seen after the local symptoms have been cured. Sometimes in a single night they will have acquired a considerable increase in size; they rarely, if ever, come to suppuration, and ought never to be considered as the effect of syphilitic poison.

Treatment of the Phlegmonous Bubo.—It has been proposed by many surgeons to treat this case as a simple glandular inflammation, tending to suppuration, by leeches, saturnine applications, rest, &c., but it must be obvious that this plan is derived from a mistaken notion; the antiphlogistic treatment promises little success unless accompanied by the antidote. Leeches may relieve pain, but their bites do as much harm as the loss of blood does good; and when the swelling has existed for several days, they will not prevent suppuration.

When suppuration has taken place, the patient is less liable to secondary symptoms than when the swelling has been discussed—not that much importance is to be attached to evacuation of the morbid matter, but there is more certainty of all the parts being freed from the disease; for an enlarged gland, which has not been brought to suppurate, may be so altered in structure by the virus, as to prevent the antidote from having its full effect upon it. Nevertheless, the syphilitic bubo ought, if possible, to be repelled, as great inconvenience is frequently produced by ulceration; besides, even in this species, the process of suppuration is sometimes tedious, and always painful.

The consequence of repelling a bubo need not be dreaded if it be discussed under the influence of the antidote; for how can matter be absorbed from a gland if the antidote be properly applied?

The best mode of discussing an incipient bubo is by rubbing into the thigh a drachm, or a drachm and a half, of the strong mercurial ointment for five or six nights consecutively. If it should not yield to this, a larger quantity is to be used; and it will be found, that almost as soon as the salivary effects become visible, the inguinal swelling will begin to disappear; it often remains stationary when only a moderate quantity of the ointment has been used, but disperses rapidly when more fully employed.

No advantage arises from rubbing in the ointment on the diseased side, it ought rather to be rubbed into the contrary side, or into the arms, if both groins are affected. Plasters are of no service during the inflammatory stage; they are more likely to aggravate than discuss the swell. When, however, the gland is in an indurated state, they may be applied with advantage.

Emetics have no effect in causing absorption of enlarged inguinal glands; and if they had, they would be prejudicial in promoting the introduction of the virus into the system.

An incipient bubo must be considered as containing a morbiferous poison; and as high living and stimulants tend to promote suppurative inflammation, without having any curative influence whatever upon the virus, such treatment is to be considered prejudicial; it is therefore best to prescribe a low diet when an attempt is made to discuss an incipient bubo.

On the other hand, as in some habits low living produces great debility, and as the quick introduction of mercury into the system in such cases is apt to increase the inflammation, it will be right to advance the diet and withdraw the mercury, or it may be moderately rubbed into the opposite thigh, or into the arms.

With a view to eradicate the virus, it has been recommended by Mr. Freake to remove the enlarged glands by excision; but this mode of treatment is more plausible than eligible, and has arisen from an imperfect knowledge of the theory of absorption. The

objections are—1st. It is not certain that the contaminated gland contains all the virus. 2nd. It cannot be reduced to general practice, as the glands are frequently so situated as to render their extirpation impracticable or dangerous. 3rd. A bubo is so frequently discussed, that the risk of suppuration does not justify the pain and danger of the operation; in short, it is a plan which cannot be relied upon, nor attended with any possible advantage.

If, on being first consulted, the surgeon find that suppuration has commenced, it will be proper, notwithstanding, to recommend mercurial friction immediately; for this will often so diminish the size of the swell as to leave it when it bursts no larger than a common boil. No advantage will be gained by waiting till complete suppuration takes place; on the contrary, the ulcer will not heal so well without the adhibition of mercury.

The same external remedies may be employed to promote suppuration in this case as in any other phlegmonous tumour; linseed-meal poultices will be the best, and the abscess ought not to be opened till it is near to breaking.

Various modes of opening these abscesses have been recommended; some open them by puncture; some by caustic; whilst others leave them to time. Some propose a large, and others a small, opening. The truth is that no precise rule can be given on this point. In the purely plegmonous bubo, where only one gland is affected, and where the skin is quite sound, it may be opened by making a small puncture in the most prominent and dependiug part; and when the matter has been squeezed out, compresses moistened with Goulard's wash should be applied, and maintained in their position by a flannel roller. In this way the part will sometimes heal in six or seven days.

Should this mode of treatment be considered as likely to prove inconvenient, the abscess may be allowed to rupture spontaneously, and be subsequently treated by poultices or soap cerate.

The result of these abscesses most to be dreaded is an extensive ulcerated surface; this seldom occurs where the skin is sound; but when it is in a morbid condition, the ulcer may not heal for six or eight months.

[Had Mr. Pearson been acquainted with the curative power of that extraordinary medicine, the iodide of potassium, in such a case, his prognosis would have been very different.]

When the superincumbent skin, the absorbent glands, and parts below, are found to be diseased, the bottom of the abscess ought to be exposed by removing the skin with a double-edged knife, carried in a circular direction around the morbid surface; dry lint may be applied to the cut edges, and the following day a linseed-meal poultice, after which the ulcer may be treated with green digestive ointment till it granulates. If after a fortnight the sore assume a marbled appearance, it should be sprinkled with red precipitate powder, dressed with red ointment, and a pretty tight bandage applied.

Particular attention is to be paid to the edges of the sore; they are to be kept soft and even by lunar caustic; and if this should not succeed, a plaster should be applied every day in which there is a small quantity of corrosive sublimate.

(To be continued.)

ON RETROFLEXION OF THE UTERUS.

A Paper read before the Medical Society of King's College, London, Nov. 18, 1847.

By Frederick John Hensley, M.B., Lond., Vice-President of the Society.

Mr. President and Gentlemen,—

The subject which I have the honour of bringing under your notice this evening is one of considerable interest and importance. The diseases of the uterus have been hitherto much neglected by the profession, and are in general but little studied by the student of medicine in this country, and consequently, the profession, as a body, are to a great extent ignorant of their diagnosis and treatment; yet, without a knowledge of uterine disease, both functional and organic, it is impossible satisfactorily to treat the numerous disorders to which the female sex is liable. It may be well then to consider the causes of this general neglect, and the means best adapted to remedy it in future.

At the root of this evil I place the want of clinical instruction in uterine diseases, a want dependent partly on the nature of the diseases themselves, which must ever render their demonstration to numerous students difficult, and in part on the natural and laudable repugnance of the sufferers to indiscriminate examination and exposure, and the delicacy with which it is the duty of every physician to conduct such investigations. It is true that the English student may find an ample field for such investigations and studies in the Continental schools, but few, comparatively, can avail themselves of such advantages; and many of those who do, and who are ill-prepared by their previous studies to make the best use of them, are apt, on their return, with a short sighted policy, to sneer at those who would rationally investigate uterine disease by the employment of such means as aid the senses,—I mean the speculum uteri, and the sound. Shocked as their English feelings are by the indelicate and indiscriminate exposure of the person in the Parisian Hospitals, and the roughness of the treatment adopted, they should distinguish the use from the abuse, and consider that such unwarrantable proceedings are not necessary concomitants of the

practice. But so long as clinical wards, devoted exclusively to the diseases of women, and under the arrangement and complete control of the professor of midwifery and physician accoucheur, are not thought necessary, or not established, clinical instruction in uterine disease cannot be efficiently given. In vain does the professor give the most lucid and natural descriptions of the diseases of the female in the lecture room,—in vain does the student ransack libraries and museums for descriptions and specimens of uterine and ovarian disease, if he has not the opportunity of investigating for himself, under the guidance of his professor, those difficult diseases—difficult I say, for whilst physiology and pathology have thrown a flood of light on diseases of the brain and nervous system; whilst auscultation and percussion have rendered the diagnosis of diseases of the chest comparatively certain, and the microscope, in revealing the minute structure of the liver and kidneys, and enabling us to distinguish the most minute changes in their excretions, has vastly improved our knowledge of hepatic and renal maladies, our knowledge of the nature, diagnosis, and treatment of uterine diseases remained till within the last few years almost stationary.

The last few years, indeed, have witnessed the establishment of clinical wards, devoted exclusively to diseases of women, in several of the larger hospitals, and a hospital has been established expressly for this purpose, which, though small in its beginning, may hereafter rival the great Continental hospitals, and has already contributed not a little to advance our knowledge of these obscure diseases. In these institutions the more advanced students have the opportunity of tracing the course, and watching the treatment of uterine diseases, far more satisfactorily than they can do in the care of out-patients, where both women and children are seen together, and where their numbers almost preclude the physican from giving that individual attention and examination which he would wish.

I trust that, though under present circumstances it is hardly possible any such plan as I have alluded to would be adopted, yet we may hope that in the plan for the new hospital connected with this College, the importance of such an arrangement will not be overlooked; then will the school of King's College, perfect in its arrangements for practical instruction, as well as eminent for the learning and eloquence of its professors, and the noble spirit which animates them, reach that eminence which, but for the deficiency of its hospital, it would long since have attained, as the first of the metropolitan medical schools.

Having myself enjoyed the advantage of holding the appointment of House Surgeon to the Hospital for Women for nine months, and subsequently that of House Physician to King's College Hospital, I have had unusual opportunities of studying uterine diseases, and have for this reason selected one of the many forms of displacement of the uterus for consideration this evening, not only on account of its intrinsic importance, but because it enables me to introduce to the notice of the Society some great improvements in the diagnosis and treatment of the maladies of this organ.

Till within the last few years very little was known of the displacement of the womb, denominated *retroflexion*. We find in authors very vague notices of it, as a pure and interesting affection. Dr. Denman is the first author who speaks of it in his treatise on Midwifery and Diseases of Women. After more particularly describing retroversion of the uterus, as it occurs in the pregnant state, which is a perfectly distinct affection from that under consideration, he says,—"The retroversion of the uterus has generally occurred about the third month of pregnancy, and sometimes after delivery; it may likewise happen when the uterus is from any cause enlarged to the size it acquires about the third month of pregnancy, but not with such facility as in the pregnant state, because the enlargement is then chiefly at the fundus. If the uterus is but little enlarged, or if it is enlarged beyond a certain size, it cannot well be retroverted; for in the first case, should the cause of a retroversion exist, the weight at the fundus would be wanting to produce it, and in the latter the uterus would be raised above the projection of the sacrum, supported by the same. Another complaint similar to that which we have been describing, and which has been called a *retroflexion*, has occurred in practice. By this term is implied such an alteration in the position of the parts of the uterus, that the fundus is turned downwards and backwards between the rectum and vagina, whilst the os uteri remains in its natural situation, an alteration which can only be produced by the curvature or bending of the uterus in the middle, and in one particular state,—*i.e.*, before it is properly contracted after delivery. A retention of urine existing at the time of delivery, and continuing unrelieved afterwards, was the cause of the retroflexion in the single case of that kind of which I have been informed by Dr. Thomas Cooper, and the symptoms were like those occasioned by the retroversion. When the urine was drawn off by the catheter, which was introduced without difficulty, the fundus of the uterus was easily replaced by raising it above the projection of the sacrum, in the manner advised in the retroversion, and it occasioned no further trouble."

The following historical notice was published by Madame Boivin, in her "Traité Pratique des Maladies de l'Uterus et de ses Annexes." "Dr. Denman's case was nearly forgotten, when an observation, forwarded by Madame Boivin to M. Ameline, and published by that gentleman in his thesis on 'Anteversion,' fixed the attention of practitioners of midwifery; since that time incurvations of the unimpregnated uterus have been often recognized, and rationally treated. We here purposely make use of the epithet unimpregnated, to distinguish deflexions of the uterus in that state from an inclination of the same organ during advanced pregnancy, which was known before. Baudelocque had correctly observed, that in certain obliquities of the

uterus, the neck deviated from the natural axis of the entire organ, in the same direction as the fundus. The same fact has been observed by Madame Lachapelle, Velpeau, and others."

Dr. Moreau, of Paris, is the only observer who notices the fact of retroflexion occurring more frequently in the unimpregnated state, than during pregnancy. Professor Tiedemann, of Heidelberg, published in 1840, some researches on what he designated the *congenital obliquity of the uterus*, an obliquity depending on an inequality of the broad ligaments by which its fundus is bound down to one side of the pelvis.

Seeing this displacement was but little known, we shall not wonder when we find the records of its detection after death to be few.

Saxtorph, in his "Animadversiones de correctione Uteri et Fœtus, in partu," says, "In a body which I opened some time ago, in the presence of the first medical men of this place, I found a virgin uterus, the fundus of which, as a congenital formation, was completely bent backwards, and which if it had even been impregnated, would on account of its faulty structure, have probably been unequally distended, and have become oblique." Dr. Rigby observes, in reference to this quotation, "The fact is interesting, but the inference about the obliquity of the uterus is wrong, the old theory on this subject, promulgated by Deventer at the beginning of the last century, having been long since proved to be incorrect."

Jahn, a German physician, in examining the body of a girl aged 14, in whom the hymen was uninjured, found the uterus bent to the right side, in the shape of a retort; the cervix uteri, which rose straight from the vagina, took a sharp turn to the right, so that the obliquely-formed fundus lay in the upper and right part of the pelvic cavity; at the point where the curvature took place, the os uteri internum, viz., the upper part of the canal of the cervix uteri, was so contracted that it would not even admit the finest probe. The os uteri externum was of the natural shape, and formed a transverse fissure.

Schreger gives the case of a young woman, aged 20, who died of consumption, and in whom the uterus was found retroflected, the fundus being turned back to the hollow of the sacrum, and to the right. The direction of the urethra was natural, and the patient had never complained of any difficulty in passing her water; she had also menstruated regularly up to the last stage of her illness.

Dr. Simpson, of Edinburgh, has for some years been carrying on his researches on this subject.* In 1844 Dr. Protheroe Smith first made out the existence of this displacement in a patient at the Hospital for Women; and since that time, both Dr. Protheroe Smith and Dr. Rigby have met with numerous cases in practice, and have proved that the disease is of far more frequent occurrence than is generally supposed, and much more frequent in the unimpregnated state, than retroversion in the pregnant.

How is it then, we may inquire, that a disease so frequent in occurrence, and so important in its consequences, has been so long overlooked or unrecognized? It arises from the defective means of diagnosis. Even in 1836, Dr. Davis, in his elaborate work on "Obstetric Medicine," very truly asks in reference to the diagnosis of deflexion of the uterus:—

"Does the supposed palpable doubling of the angle of flexion by the finger furnish sufficient evidence to the practitioner of the continuousness and identity of the tissues forming its two sides? If not, it should of course follow that the tumour, supposed to be the fundus of the deflected uterus, might really prove to be one of morbid growth, either from the body of that viscus itself, or from any other part or organ in the neighbourhood. Hence the diagnosis of these deflexions, when of long standing, and become actually chronic in their essential character, must always, in the author's apprehension, present a subject of considerable doubt and difficulty." Dr. Davis having no other means of diagnosis, it is no wonder that he should arrive at the very erroneous conclusion that retroflexion of the uterus was a very rare occurrence.

Dr. Simpson, in introducing his instrument (the uterine sound,) laid down the four following propositions, the truth of which is so obvious, that I deem it unnecesssary to enter into further proofs respecting them.

"1. The general and local functional symptoms of disease of the uterus are such as enable us to localize, without enabling us to specialize, the exact existing affection of the organ.

"2. In almost all instances of diseases of the uterus, it is only by the physical examination of the organ itself, that we can distinguish the precise nature of the existing affection, and fix its character, extent, &c.

"3. The physical examination as formerly practised, seldom enables us to ascertain accurately the organic condition of more than the cervix and lower part of the body of the uterus.

"4. It is possible, by the use of a rod or bougie, introduced into the uterine cavity, to ascertain the exact position and direction of the body and fundus of the organ, to bring these higher parts of the uterus in most instances within the reach of tactile examination, and to ascertain various important circumstances regarding the os, cavity, lining membrane, and wall of the uterus."

The bougie proposed by Professor Simpson, and called by him the *Uterine Sound*, is an instrument provided with a flat handle, having one surface roughened,—that corresponding to the concavity of the instrument. Its shaft is about nine inches long, and terminated by a roundish bulb, about one-eighth of an inch in diameter; the shaft is composed of flexible metal, to enable us to alter its curvatures; it gradually tapers in its thickest part; it is about one-fifth of an inch in diameter, corresponding in size to No. 8 silver catheter; in its thinnest about one-tenth of an inch,

* Dr. Rigby has also published some papers on this subject in the 13th Vol. of the *Medical Times*.

in size, corresponding to No. 3 catheter. This instrument is graduated and marked at two and a half inches from the bulb, by a projection on the convex surface of the curve, to enable the finger to judge of its having passed to its full extent. The natural length of the cavity of the uterus is two and a half inches, and it forms a slight curvature forwards and upwards. The sound is passed with greater ease than the catheter, and produces less uneasiness than that instrument, certainly much less than the passage of a catheter in the male subject. The mode of passing it is as follows:—The patient is placed on the left side, with the knees drawn up; the forefinger of the left hand is then introduced to find the os uteri; having done so, the sound is passed, held lightly between the finger and thumb of the right hand, along the forefinger, and guided by it, is insinuated into the os, and gradually and gently pushed along the cervix into the cavity of the uterus; in some cases the canal of the cervix or the os internum is so small as not to allow it to pass, it must then be first dilated.

The application of the uterine sound has opened a new era in the history of uterine diseases; by its means, cases before imagined to be malignant affections of the os and cervix uteri have been proved to be nothing more than extreme congestion, produced by retroflexion of the fundus,—long standing affections pronounced by eminent men to be incurable; fibrous tumours have been demonstrated to be retroflexions, and removed by restoring the fundus to its natural situation; whilst other tumours, of whose connections it was difficult if not impossible to be certain, have been shewn to be ovarian and unconnected with the uterus. But time will not permit me to enter into the numerous applications and uses of the uterine sound.

We must now proceed to inquire what are the symptoms produced by this displacement, and the causes which lead to it?

In some cases no appreciable symptoms are produced, except perhaps a greater flow of the menses, and a greater tendency to abortion in the married female, whilst in others the symptoms are exceedingly distressing and complicated. It is in most cases difficult to trace the first origin of the affection, but in some instances in which diligent enquiry has succeeded in doing so, the patient would appear to have been cognizant of some depresssion or falling down of the body of the womb, sometimes occurring suddenly, in other instances more gradually progressing, in the former producing alarming sympathetic affections, as nausea and vomiting, and actual syncope, together with more or less pain referred to the groin or sacrum. The retroflexion increasing or becoming permanent, produces some pain and difficulty, or frequency in micturition, though it never leads mechanically to retention of urine. The patients complain likewise of a dull aching constant pain in the sacral region, probably arising from the pressure of the fundus on the sacral nerves, since it is often immediately removed on raising the fundus; the pain often shoots down one of the thighs, there is also a sense of weight and bearing down towards the rectum, much increased by the act of defœcation. Advice not being sought at this period, or the deplacement being overlooked, other more serious symptoms manifest themselves; menstruation becomes highly painful, the discharge is generally increased in quantity, and clots and shreds denoting irritation are voided,—in short, dysmenorrhœa is set up. In the intervals an abundant leucorrhœal discharge is usually present.* These symptoms cannot exist without the patient's general health suffering more or less; the stomach, which has an intimate sympathy with the womb, becomes disordered, the appetite is capricious and irregular, the tongue loaded, the bowels constipated, the patient's spirits are depressed and irritable, and a variety of nervous hysterical affections are apt to occur. Such symptoms as these, though they do not prove the existence of a displacement of the womb, yet evidently localize the affection there, and warrant further examination per vaginam, which alone can enable us to determine with certainty the existence of this displacement, and to rectify it.

In examining a case of retroflexion of the uterus during life, the finger can frequently reach a firm globular mass, situated behind the cervix uteri, between the rectum and vagina; this is the fundus uteri, which is bent downwards and backwards, the os uteri instead of being forcibly dragged upwards and forwards behind the symphysis pubis as in retroversion, is little, if at all, removed from its natural situation. At first we may not be able to determine this globular mass to be connected with the uterus at all; it may appear to be merely a scybalous collection in the rectum, hence we should always if possible, before examining a patient, prescribe an aperient or an enema to remove this source of error. In other cases the tumour may be too high up to allow the finger to trace its continuity with the cervix, whilst in others again, the point of curvature being low down, the fundus is much below the os uteri, and its continuity is easily traced by the experienced finger.

The exact position of the retroflexion varies considerably in different individuals, and even in the same individual, at different times; the point of curvature may be so high up that a very small portion of the fundus is all that is bent down. On examination per rectum we feel the same globular mass through the anterior wall of the intestine, and being able to reach much higher up in this direction than per vaginam, we can frequently verify or correct our first impression.

* In cases immediately following abortion, reproduced by a too early recurrence to ordinary occupations or undue exertions, I have observed the hæmorrhage to continue a longer time than usual, and even become constant.

It is, however, by the use of the uterine sound, that we can obtain sure and valuable information of the displacement of the womb. In a case of retroflexion, on passing the instrument in the natural direction upwards and forwards, it becomes almost immediately arrested; but on turning its point in the contrary direction, backwards and downwards, it will pass readily along the cervix uteri, and then glide downwards and backwards to its full extent of two inches and a half. The point can now be felt distinctly in the centre of the tumour, through the posterior wall of the vagina, or the anterior of the rectum, thus proving it to be the fundus uteri in this unnatural position. Nor is this all, by turning the instrument gradually and gently round, so as to bring the point upwards and forwards, at the same time assisting the elevation of the fundus with the forefinger of the left hand, we shall find that the tumour disappears, it can no longer be felt, the fundus is restored to its natural situation, and retained there by the sound without it; the patient will often be immediately relieved from the constant pain and uneasiness from which she has previously suffered in the sacral region.

In some instances the mere restoration of the fundus to its position is sufficient; it remains there permanently, even after the withdrawal of the sound; in others for a short time only; but in many cases, especially in those of old standing, the disposition of the fundus to return to its unnatural position is so great, that it requires the handle of the sound to be held pretty firmly to prevent its turning it round, and as soon as the sound is withdrawn, the fundus again retroflects, and we can again trace the tumour as before.

The examination and passage of the sound produces in many instances little or no pain, until we elevate the fundus, when the instrument, pressing on the ovary, which we shall afterward see is extremely apt to become congested and inflamed in consequence of the displacement, occasions severe pain, which, however, immediately ceases on our completing the restoration. In the examination per rectum the pressure of the finger on the fundus above occasions no pain, but if we elevate it, the patient immediately complains, and by passing the finger beyond the depressed fundus, we can discover the exact seat of pain to be the posterior and upper part of the fundus, in the situation of the ovary, which we can often feel as an oval body. These last symptoms are dependent on the inflammation of the ovary, and cannot, therefore, be regarded as essential to retroflexion of the uterus, but as the consequence of a complication. It occurs, however, sufficiently often, to render it advisable in all cases of oophoritis of long standing, to examine carefully into the position of the uterus.

In some cases the canal of the cervix is so small as to prevent the passage of the sound: in such a case the dilator must first be employed, until a sufficient passage has been obtained. Dr. Rigby is of opinion that this extreme narrowness of the cervix is rather owing to a congenital formation than to the bent state of the fundus, which last, however, he regards as sufficient not only to obstruct the free discharge of the catamenia, but to prevent conception.

I will here introduce to the notice of the Society the dilator which I am in the habit of employing, and which I believe to be the most efficient; it is that invented by Dr. Protheroe Smith. The power of the screw is the moving power, and it is capable of being regulated at the pleasure of the operator. After one or two dilatations we shall be able to pass the sound through the cervix, and ascertain the state of the fundus.

If any of you are still sceptical of the benefits to be derived from the employment of the sound, let me quote a passage from a paper read by Professor Simpson before the Dublin Obstetrical Society, shortly after he proposed his instrument to the profession,—he says, "In one of the first cases in which I recognized by the uterine bougie, the existence of retroflexion of the unimpregnated uterus, the patient had some years previously been doomed by the highest obstetric and pathological authorities in England, as suffering under the first stage of scirrhus uteri, the displaced fundus having been mistaken for a carcinomatous tumour. The uterine displacement was easily rectified by the use of a wire pessary, worn for some months in the uterine cavity, and the patient is now in the enjoyment of the best of health. I have seen other cases of the same mistake with the same curious but common form of uterine displacement."

It was only the other day that my friend, Dr. Protheroe Smith, informed me, that several cases, which had been sent to him as cases of fibrous tumour of the womb, had proved on examination, nothing more than retroflexions. The celebrated case of Miss Martineau, which attracted so much attention in the literary world, and which was afterwards published by her medical attendant, Mr. Greenhow, of Newcastle, was an instance of retroflexion of the womb, complicated with a small polypus growing from the interior, and inflammation of the left ovary; the enlargement of the body and fundus was the effect of the displacement. Had the true nature of the malady been detected in the first instance, and the fundus restored to its position by the sound after the removal of the polypus, the talented sufferer would have been spared many years of suffering and useless drugging. The ultimate and gradual restoration of the organ to its normal situation, which took place after the bowels had been unloaded, and the general health improved by purgatives, and which occasioned the patient's restoration to health and to society, would not then have been attributed to the Mesmeric influence.

(To be continued.)

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, JANUARY 12, 1848.

In commencing a new volume of the Journal of the Provincial Association, we would express the hope that the recommendations of the Publications' Committee have, during the past year, been carried out so as to meet with the approbation of the members generally.

As far as the character of the original communications is concerned, we feel confident that, without disparagement to the papers published in former volumes by many valued contributors, the increase in the size of the Journal has been most beneficial. Very many of the papers and cases inserted in the pages of the volume just completed are of the highest interest and value, and will bear comparison both in number and importance, with those published by any of our contemporaries. We claim no merit for ourselves on this account, but it is a duty which we owe to the energy and ability displayed by the members of the Association, and others, by whom the papers have been furnished, to record how much the *Provincial Journal* owes to their continued and zealous support.

The position which one of our valued correspondents has occupied since the month of September last, forbids us to say more than that we hope the information selected from various sources for the General Retrospect during the past year, has been acceptable and useful to the members of the Association; but we cannot let this opportunity pass, without expressing to Dr. Ranking, of Norwich, the obligations under which the Journal is placed, for the valuable matter furnished to that department previously to his official appointment as Foreign Editor.

The excellent reports of cases treated at the Birmingham Queen's Hospital, the West Norfolk and Lynn Hospital, the St. Pancras Dispensary, &c., render it a source of regret that similar reports have not been more extensively obtained from other similar institutions. We earnestly request that such of our readers as are attached to hospitals and dispensaries, more especially those situated in the provinces, will from time to time contribute the records of their cases, and thus enable us to give to this department of the Journal that prominence during the present year, which is requisite to make it a faithful record of provincial practice.

The volume just concluded contains the proceedings of several admirable Provincial Medical Societies. Among others those of the Branch Associations;—the Bath, the Birmingham, and the Reading Pathological Societies;—the Sheffield Medical Society, &c., in addition to papers and cases read at other Societies, inserted among the original communications, There are other institutions in the provinces, the record of whose proceedings we should be glad to see preserved in the pages of the *Provincial Journal.*

To these points we beg to direct the attention of the members of the Association; they will bear in mind that every addition of this kind will tend to advance the reputation and to promote the welfare of the Association; to render its Journal of more extended usefulness; and by developing and making known the resources of our provincial institutions, to prove, that however highly our metropolitan brethren may stand in public estimation, and however some of them may be disposed to undervalue the professional knowledge and ability to be found in the country, we have yet among us physicians and surgeons whose attainments are in no way inferior, although, perhaps, their opportunities for the public display of them in Halls and Colleges may be less frequent.

Reviews.

On Pulmonary Consumption, and on Bronchial and Laryngeal Disease, &c. By Sir Charles Scudamore, M.D., F.R.S., &c. &c., London: 8vo. pp. 259.

Although some parts of this volume are written in language so simple as to be intelligible to the general reader, there are so many other parts that may fairly be regarded as intended for the profession, that it would be very unjust to stigmatize the whole as a popular dissertation. There is, it is true, an occasional

explanation of terms which clearly indicate that the author had no wish to limit his observations to the perusal of his Æsculapian brethren. In fact, he candidly expresses his "hope that a summary of anatomical and physiological description of the organs and textures chiefly concerned may not be unacceptable, *even to his professional reader.*" It is to be lamented that a titled physician, a Fellow of the London College, and a F.R.S., should have pursued the course of thus addressing the public, where the motives by which he may be influenced are so liable to misconstruction. The *suspicion* of being a popular writer upon a strictly professional subject should be sedulously avoided by every right-minded practitioner. Still there is, in our opinion, a degree of honest feeling and truthful investigation pervading the book, that legitimately entitles the author to attention.

The first division of the treatise consists of an outline of the nature, symptoms, and treatment of pulmonary phthisis. The second division (which has been previously published,) consists chiefly of a history of the writer's experience with regard to the beneficial effects of "inhalation" in certain diseased conditions of the lungs. The cases by which the curative influence is sought to be established are explicitly related; there does not appear to be any anxiety to *magnify* the favourable results. The circumstances under which the inhalation has been tried, the mode of its application, and the consequences produced, are all plainly specified. The treatment, combined with the inhalation, is also faithfully recorded, and, we think, may be read with advantage by every member of the profession. The medicinal agents especially recommended for inhalation, are iodine and conium. In some instances of extreme irritability, hydrocyanic acid is stated to have been substituted for the iodine with decided advantage.

It is unquestionably the duty of every practitioner to avail himself of all authentic information that may enable him to mitigate the urgent sufferings of consumptive patients, however hopeless his efforts may be with regard to *permanent* restoration. We have no right to doubt that Sir Charles Scudamore has carefully tried the practice which he advocates, and that it has, on many occasions, been eminently successful. He has, it is true, placed himself in a false position, and thus weakened the force which his observations might otherwise have had with his professional brethren, but we will charitably hope that the error has been simply one of judgment, and give such credit to his investigations as they may otherwise seem to merit. If the latter part only of his volume had been published, it would, probably, have been more agreeable to the medical inquirer, inasmuch as the former part is principally a summary of what is already known. With this remark we conclude our notice of a book, many pages of which, we think, will well repay perusal.

Answer to the Religious Objections advanced against the Employment of Anæsthetic Agents in Midwifery and Surgery. By J. Y. Simpson, M.D., F.R.S.E., Professor of Midwifery in the University of Edinburgh, and Physician Accoucheur to her Majesty in Scotland. Edinburgh, 1847. 8vo, pp. 23.

This excellent pamphlet contains a reply,—in our opinion unanswerable,—to certain religious objections advanced against the use of æther and chloroform in obstetric practice. These objections are chiefly based on an erroneous view of some passages of scripture, and Professor Simpson has ably and learnedly set forth the source of the misconception by which many estimable persons appear to have been influenced. We would earnestly recommend the perusal of his observations to all who may entertain objections to the employment of anæsthetic agents on religious grounds. Their general administration on other grounds,—physological or pathological,—rests on evidence of an entirely different description, and must be ultimately established or rejected by the accumulated experience of many competent observers.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

[In order that the newly admitted members of the Association may become acquainted with the main objects of this inquiry, and at the same time be enabled more readily to contribute towards their attainment, we here reprint the questions which have been specially proposed for consideration.]

1. Whether stimulants (spirits of turpentine, alcohol, ammonia, &c.,) are useful in cases of burns and scalds; and if so, in what cases, and in what manner?
2. What is the value of cold applications in burns and scalds? Are they admissible in burns of great extent? In burns of small extent is cold water better than any other application?
3. What is the experience of members as to the value of cotton and flour as a dressing for burns and scalds?
4. What internal remedies are best immediately after extensive burns and scalds?
5. How far do situation and extent affect the cure of burns and scalds?
6. What are the best methods of preventing cicatrices after burns and scalds?
7. What are the *post-mortem* appearances after burns?
8. What is the prognosis in burns and scalds?
9. What is the best method of remedying cicatrices after burns and scalds?
10. What directions ought to be given to the public for the prevention of burns, and for their treatment in the interim between their occurrence and the arrival of a practitioner?

11. Enumerate any practical rules for the management of extensive burns, as regards the healing of the wound, the repression of granulatiohs, and the preservation of the strength of the patient.
12. Give cases of death during apparent recovery from burns.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,—During the few days which have elapsed since the last number of the Journal was published, I have had the satisfaction of receiving several communications on burns, and promises of many others. Hence I am led to hope, that as soon as this busy season has passed over, there will be numerous contributions from the profession respecting their experience in the treatment of burns. I beg to repeat that every contribution will be acceptable, and will serve to promote the inquiry. If a practitioner states that he has confidence in flour or cotton, and that he uses them constantly in his practice, the information is worth recording; for though many would not be disposed to attach much importance to individual experience in burns, or in any disease, yet every one will admit that the *collective* testimony of a body of observers on any particular remedy or question, is highly deserving of consideration. But if it should be found that a large body of practitioners treat burns successfully by those means which simply exclude the air, then, I apprehend, this *fact* becomes a strong presumption in favour of a mild and unirritating treatment, and against the use of strong stimulants. On the other hand, if it should appear that the employment of stimulants (on Kentish's plan,) is adopted by many hospital surgeons, as well as by those residing in neighbourhoods where there are explosions in the collieries, then it is a presumption that this plan of treatment is valuable. If, however, it should hereafter appear that burns get well nearly as rapidly under one plan as under another, provided the air be excluded from the burnt surface, then the disclosure of this *fact*, by numerous returns from the provincial practitioners, will tend greatly to the amelioration of the treatment, by making observers try different plans, and keep notes of their success. During the remainder of the winter there will be a great many cases of burns under the care of the readers of your Journal, who if they were to make brief memoranda of them, stating the age, sex, whether a burn or a scald, and with what;—part injured, extent of injury, and amount of surface injured;—treatment, continuance of the pain, and duration of the cure, would by this means be procuring data for a careful estimate of the relative merits of different methods of treatment. Where corresponding parts of the body are burnt to an equal extent, it is highly desirable to treat them by opposite methods, and thus ascertain which is the best plan. The following example of the latter mode is a highly interesting one; it was communicated to me by Mr. P. H. Holland, of Manchester, a gentleman whose name is widely known from his devotion to sanitary inquiries:—

"The cook of P—, Esq., barrister-at-law, on the 17th of November, 1847, scalded both her feet with equal severity, by upsetting a pan of boiling water. She applied a rag dipped in *cold* spirit of turpentine to the right foot, covering it with a poultice of cow-dung. She had not turpentine enough in the house to apply to the other foot, she therefore covered it with a poultice of cow-dung only. Mr. Holland saw her about three hours after the accident, when she complained of severe burning pain in both feet, especially in the right. On examination, he found the right foot *not* vesicated, while the left was vesicated nearly over the whole instep. At this time the cow-dung was ordered to be removed, and flour applied to both feet. The feet were then enveloped in cotton wool, and both the cotton wool and flour kept applied for two days, at the end of which time the right foot (the one to which the turpentine had been applied,) was quite well, but the vesications on the left foot had been followed by a suppurating surface, which was very painful, and did not heal for three days."

The above case is particularly interesting. It is common to hear persons say that it is no proof of the superior efficacy of one plan of treatment over another, when cases are mentioned of great success, obtained by different or opposite remedies. But no objection can surely be taken to an experiment like the above. The two feet were scalded equally severely, at the same moment, and under precisely similar circumstances. Both were treated alike, except that the first had been previously washed with *cold* turpentine. The one so washed healed much sooner than the other, and probably with less pain. If the feet of two *different* persons had been so scalded,—those of one person being treated *with* turpentine, and those of the other *without* it,—it would have been said that the difference in the habits of the persons' bodies, or in the severity of the scalds, was the cause of the difference in the results. With a view to the clearing up of the more disputed points in burns, I intend to perform some experiments on my own person. It appears to me that a few simple experiments may do away with a great deal of the diversity of opinion which prevails on many points in their treatment.

In my last letter I omitted to allude to the use of the "impermeable piline" in burns. Mr. Markwick, the inventor of this substance, wrote to me on the 20th of October, as follows:—

"A few cases of burns and scalds, of the first and second degree, have lately come under my notice, in which the "impermeable piline" has answered admirably well in relieving pain, and effecting a speedy restoration of the parts to their natural and healthy condition. Indeed, from the experience I have as yet had, I believe it will be found far preferable in every respect to the old remedies,—flour and cotton wadding." Mr. Markwick forwarded some of the material to be experimented with. I have put it into the hands of Mr. Bowring, House Surgeon to the Manchester Royal Infirmary, and lately House Surgeon to King's College Hospital, London, who will be able to report upon the efficacy of the material recommended by Mr. Markwick.

The next communication is from Mr. Sweeting, of Abbotsbury, Dorset, who observes that,—"An experience of forty years has led to my conviction that the best possible method of treating burns and scalds, is to carry out, *to its full extent*, the plan originally suggested by Dr. Kentish, which is not only valuable in practice, but founded on pure philosophical principles; all others I believe to be, at best, empirical."

The next letter is from Mr. Pope, of Cleobury Mortimer. The numbers refer to the queries in a late number of the Journal :—

Cleobury Mortimer, December 15th, 1847.

Dear Sir,—I hasten to lay before you the result of my practice in burns and scalds.

1. I have long disused stimulants.
2. Cannot say.
3. Flour applied so as effectually to exclude the air, mixed with a small quantity of Calamina præparata, I have found of the greatest service.
4. Mild opiates.
5. Cannot say.
6. Answered under third question.
7. Cannot say.
8. The absence of thirst; for when insatiable thirst appears it is the precursor of death.
9. The best method to prevent them is to treat as in third question.
10. To cover the burns with flour.
11. If the atmospheric air has been carefully excluded, granulations requiring repression seldom take place. If debility require it, bark and wine may be requisite.
12. I have seen instances of death, particularly in young children, from slight burns,—I should think from nervous excitement.

I am, yours respectfully,

THOMAS POPE.

S. Crompton, Esq.

Mr. Pope having stated in his reply to the first question that he had long disused stimulants, I thought it probable that he would be able to give some interesting facts respecting the circumstances under which he was led to use flour instead of stimulants, I accordingly wrote to him to make the enquiry, and he very obligingly sent me a second letter, from which I make the following interesting extract :—

"I was determined to give it (flour,) a fair trial in the first case that occurred, and this, fortunately, was soon. The subject was a fine boy, of about four years old, and most extensively burned on the back, nates, penis, scrotum, hypogastrium, arms, and hands, so much so that under any other mode of treatment death must have been inevitable; but the poor little fellow's sufferings were wonderfully assuaged by the flour-treatment, which was so applied as effectually to exclude the atmospheric air; the healing process went on so admirably that the cure took place without the use of caustic, and without occasioning the usual peculiar cicatrices of burns. This, I think, is a happy contrast to Kentish's plan, for had the latter, or any of the others then in use, been adopted here, death would have soon ensued; and where they are used in extensive burns, and recovery follows, the latter is tedious, harassing, and painful, requiring frequent cauterization, and leaving unseemly and annoying cicatrices."

The next communication, from Mr. Gall, of Ripley, in Surrey, an advocate of the use of cotton, will be read with interest :—

Ripley, Surrey, Dec. 16th, 1847.

Sir,—I trust your appeal to the members of the Provincial Medical and Surgical Association will meet with the attention it deserves, and hasten to contribute my humble mite to the amount of information you will doubtless receive, on the important subject of burns and scalds. I shall take the questions in the rotation of your letter.

1. I have no experience of the use of stimulants.
2. Nor of cold applications; but should say they are not safe in burns of great extent.
3. I have only recently used cotton, but from two cases which have lately occurred, am so much pleased with its effects, that I shall always keep a supply ready for use. They were cases of severe burns of the arm and hand of children, from falling into the fire. The arms were enveloped in cotton and healed very rapidly: With flour I have had reason to be very little satisfied.
4. I think laudanum in full doses frequently administered, the best remedy for the state of collapse caused by severe burns.
5. Burns and scalds are dangerous in proportion to the extent of surface affected, more than in proportion to the severity of the burn with respect to depth. Burns of the thoracic and abdominal regions are more dangerous than of the extremities.
6. Cicatrices *will* occur if the whole thickness of the skin is destroyed.
7. I do not know.
8. Unfavourable if affecting a large portion of the thoracic or abdominal regions, or the anterior part of the neck and face. The danger is greater, the younger the subject.
9. I have no experience on this point.
10. To clothe children in the winter in outer garments of cloth or woollen stuff. To do nothing to the burn or scald when it occurs, until they have procured medical aid. The danger of delay is much less than what would result from injudicious meddling. The less a burnt surface is meddled with or exposed, the better.
11. The treatment I have hitherto adopted in extensive burns, since giving up flour, has been to cover the surface with lint, saturated with linseed oil and lime-water soap. If the burn is extensive and the patient is collapsed, this should be warmed. Once applied it should be allowed to remain as long as possible, until suppuration has taken place, and the discharge has become offensive. I have seen extensive burns do very well under this treatment. The strength should be supported by a generous diet, as soon as the first febrile action has passed off. Great care should be taken not to exhaust the strength by purgative medicines. The bowels are usually constipated at first, but it is better not to be too hasty in removing this, which seems rather a curative effort of nature than a disease. The Liquor Ammoniæ Acetatis, with a slight excess of ammonia, is a useful medicine in the febrile stage. When suppuration is established, Infusum Cinchonæ, or quinine. Where there is an extensive granulating surface I have seen the water-dressing of great service,—pieces of lint dipped in warm water, applied to the part, and covered with oiled silk. This dressing should not be frequently changed. It may be left on two, or even three days with advantage. When, however, there is a large surface of newly-formed cuticle, I have found it necessary to discontinue the water-dressing, and have used the calamine cerate with good effect. Poultices are decidedly objectionable, at each removal I have seen them bring off portions of newly-formed granulations, and the surface of the sore covered with blood. Changing the dressings is at all times in these cases a very painful process, and I have no doubt that much mischief is often done by the too frequent renewal of them. Having the dressings on two or three days has the appearance of neglect, but in this case it is a "most tender mercy," and contributes much to the comfort and recovery of the

patient. Under this mode of treatment the granulations will seldom be excessive. It has appeared to me that exuberant granulations are the result of want of power in the system and are best remedied by means calculated to improve the strength.

12. I do not recollect having met with any such cases.

Trusting and believing that much good will result from collecttng the experience of the profession on this and other snbjects,

I remain, Sir, your obedient servant,

A. C. GALL.

S. Crompton, Esq.

Mr. John E. Erichsen, of London, Lecturer on General Anatomy and Physiology at the Westminster Hospital, has forwarded to me a pamphlet containing important remarks on "The Pathology of Burns," an abstract of which I will prepare for publication in the next number of the Journal. Much light may be thrown upon the treatment of burns, by a closer attention to the morbid anatomy of persons who have died of them. I would suggest that it is desirable that no opportunity be allowed to pass by of obtaining a *post-mortem* examination of cases of death from burns and scalds.

I will conclude this long communication with the following extract from a letter which I have received from Mr. Hunt, of Herne Bay, a practical observer:—

"My experience in burns and scalds has been very limited; I always use flour, and have never lost a patient by such an accident. My *rationale* is to prevent the access of air to the raw surface, and to supply a convenient dressing for extensive sores. Both of these indications are carried out by the flour dredger. Internal remedies, of course, I administer, as circumstances require, bearing in mind the shock the nervous system has received by the accident, and the loss of cutaneous exhalation from the surface where a large area of skin is destroyed."

Mr. Hunt adds, that his remarks are not worthy of publication. In this I differ from him; I think that these brief declarations of their methods of treatment, by provincial practitioners, are very desirable. Further, I cannot divest myself of the impression, that an accumulation of them, from fortnight to fortnight, in the pages of your Journal, will, in the course of six or nine months, constitute a mass of evidence which may be safely used for the purpose of induction. If it were possible to obtain *numerical* returns, such as we see in the works of Louis, I admit that they would be far preferable to general statements. But the world has produced *but one* Louis.

I am, Sir,

Your obedient servant,

SAMUEL CROMPTON.

71, Grosvenor Street, Manchester.
December 22, 1847.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY,

September 2nd, 1847.

Dr. MACKAY in the Chair.

Dr. Mackay exhibited a specimen of Bright's disease of the kidney, taken from a patient who died of puerperal mania.

ANÆMIA.

Dr. Mackay also brought before the Society a heart, presenting slight enlargement of the right auriculo-ventricular opening, the only morbid appearance observable in a patient who died of anæmia at 27 years of age. The principal features after death were extreme pallor of the tissues, particularly of the brain, and serous effusion into all the serous cavities in considerable quantity.

DISEASED BLADDER.

Dr. James Russell exhibited a case of diseased bladder in which the mucous membrane was nearly removed by ulceration, with great hypertrophy of the muscular tissue. The patient, a lady, 54 years of age, mother of seven children, was of delicate constitution, and liable to frequent febrile attacks. She had one of these attacks in April of the present year, which was attended on the fourth day with discharge of bloody water; there was no pain on micturition, but great prostration, and a dull pain in the loins. Mr. Palmer examined the urine, which was natural, except the presence of blood, but not in any large quantity. Calming medicines, uva ursi, and tonics, restored her health. July 23rd. She was again in bed, with hot skin, quick pulse, and every symptom of fever. Salines were followed by an improvement in her state, and on August 3rd she commenced mild tonics. She seemed progressing favourably till the 13th, when bloody urine again occurred, attended with great pain in passing. She was extremely feeble, had pain and tenderness about the loins, and her pulse was very quick and irregular; tongue red and chapped; the urine contained a very considerable quantity of dark-coloured blood, and she had difficulty in passing her water. For many years she had not perfectly retained her water, which escaped by night into the bed; this was dated to her first confinement. On the 16th the pain had greatly increased. On the 18th she was much worse, and was in great pain; nearly a pint of urine, resembling raspberry cream in colour, was drawn off by the catheter. By examination per vaginam by Mr. Hodgson and Mr. Russell, portions of the bladder were felt quite thick and hard, which gave the impression of the presence of a tumour, probably malignant; other portions of the bladder were distinguished to be thin and natural. The os uteri was normal. The catheter was subsequently used night and morning, with great relief. She sank and died early on the 21st.

Sectio cadaveris eighteen hours after death:—Body much emaciated; very small quantity of blood in the vessels. Abdomen alone examined, of which all the organs were healthy, with the following exceptions:—

The *kidneys* were large and flabby, and much injected, their pelves and calices much distended; the mucous membrane injected, but not softened; the pelves contained some turbid urine, very ammoniacal, and apparently mixed with pus; whitish yellow spots were scattered through the substances of the kidneys; in these spots the tissue was very soft, but no pus could be expressed, in one or two places the spots were collected to form a whitish mass of softened tissue, nearly the size of the end of the little finger; the ureters at their origin healthy. Bladder very much thickened; its muscular bundles very much developed, and projecting, to form a very coarse net work; the posterior wall, where the hypertrophy was greatest, was mostly stripped of its mucous membrane; in other parts of the inner wall were numerous prominent whitish spots, as of commencing sloughy ulceration; the entire inner surface was of a deep purple colour, from sanguineous injection.

ANEURISM OF THE AORTA.

Dr. Fletcher brought forward two specimens of aneurism, taken from the body of the same patient, one of the arch of the aorta, and arteria innominata, another of the aorta and cœliac artery.

Mrs. Humphries, aged about 48, became a dispensary patient under the care of Dr. Fletcher, on the 15th of January, 1847. She was thin, but stated that she had much emaciated lately; she had passed a very active life, and been much in the habit of lifting heavy weights. She began to suffer from symptoms of indigestion and pains about her bowels about eighteen months since, and about ten months since a small pulsating tumour was discovered in the situation of the epigastrium, which was capable of being moved from side to side. On examination the tumour was found hard, very uneven in its shape, moveable, and pulsating, and in whatever position it was placed the pulsations were equally general and intense. At the base of the neck there was another pulsatiug tumour, situated under the sternal attachment of the right sterno-mastoid muscle. The pains in the abdomen and chest which the patient suffered from were so continual and intense, that an anodyne treatment was demanded, and she obtained some relief by taking full doses of Battley's Liquor Opii; this, together with attending to the bowels and perfect rest, formed the general plan of treatment up to the time of death, which took place after very much suffering and emaciation, on the 22nd of June, 1847.

Post-mortem examination June 24th, about forty hours after death. The head was not examined. *Chest*:—Heart generally rather dilated and hypertrophied; the arch of the aorta and the arterior innominata dilated into a pyramidal-shaped aneurismal sac, which extended up into the neck an inch above the right sterno-clavicular articulation, giving off at its apex the right common carotid, and right subclavian arteries; the left carotid and left subclavian arteries were given off from the dilated arch; the artery had its usual diameter directly after giving off the left subclavian; lungs normal; numerous adhesions of both pleuræ. *Abdomen*:—Liver congested, and putting on the nutmeg appearance; spleen and pancreas healthy; stomach and intestines healthy. At the origin of the cœliac artery, the aorta, and the cœliac tract, were dilated into a circular aneurism, of the size of a large orange; its posterior portion corroded the bodies of the first, second, and third, lumbar vertebræ; anteriorly the aneurismal dilatation extended into the trunks of the gastric and splenic arteries; the hepatic was given off above the common trunk which divided into these two arteries, which were each dilated, so as to be able to contain a large walnut, and gave the very uneven surface to the anterior part of the aneurism; the arterial system was healthy in other respects. Viscera of the pelvis healthy.

Dr. Fletcher said that it appeared that these aneurisms had commenced, and grown by general dilation of the coats of the arteries, most probably first commencing from great exertion.

ABSCESS OF THE PANCREAS.

Dr. Fletcher brought before the society a specimen of abscess of the pancreas, which had been taken from the body of a gentleman who had been a patient of his since December, 1846. The appearance was that of a man much addicted to eating and drinking. He was very corpulent, yet he stated that he had been unwell some months, and had gradually lost flesh, which he substantiated by referring to the loose state of his clothes. He complained of great pains about the epigastrium, and distention after eating, and continual dull pain extended across the belly, between the epigastrium and the umbilicus, into each hypochondrium; he complained also of great and obstinate constipation, and that the only relief he experienced was from purgative medicines, which had the effect of affording him almost perfect ease from his distressing pains, whenever a full action of the bowels was obtained. The urgent symptoms were vomiting and pain in the situations above described, attended with constipation of the bowels, which led to the supposition that some obstruction existed in the course of the intestine. A careful examination of the abdomen was made, but the state of obesity was so great, that it was not probable that anything could be discovered, even if a large tumour had existed. This state of things continued without alteration, except the occasionally longer temporary relief produced by purgatives, and that now emaciation had gone on to a great extent, which had reduced the patient exceedingly, but yet examination of the abdomen detected no tumour as the cause of obstruction. The fæces and urine maintained a natural appearance. About the latter end of May the patient had become so feeble, that he was obliged to keep his house, and soon after this his room, the prominent and urgent symptoms of his case still continuing the same. About the end of June the constipation became less urgent, and the motions altered in character; they became very fœtid, and appeared as if mixed with bloody matter from far up in the course of the intestine. The sickness subsided, and he took abundantly of nourishment, but he became weaker, hectic fever set in, and he died on the 25th of August.

Post-mortem examination twenty-four hours after death. The head was not examined. Contents of chest healthy. *Abdomen:* Liver enlarged, much congested, and having the nutmeg appearance; spleen healthy. Pancreas large, and degenerated into a purulent mass, having none of its healthy structure left; the large extremity had ulcerated into the duodenum at its inferior curve, through which the pus must have passed into the intestines. The stomach was much distended; intestines healthy, except the perforation in the duodenum; contents of the pelvis healthy.

Dr. Fletcher said that the symptoms of obstruction of the intestine would be easily explained by the pressure of the pancreas upon the duodenum, previous to the bursting of the abscess situated in it into the cavity of that intestine.

Foreign Department.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE, PARIS

LITHOTOMY AND LITHOTRITY.

The discussion of the comparative merits of lithotomy and lithotrity still continues to occupy attention. The long reply of M. Civiale, to the objections of Velpeau, Roux, &c, comprehends three distinct parts. In the first he endeavours to answer Velpeau, Blandin, and Malgaigne; in the second and third parts he treats of two very important questions,—those of the *explorations* and the *relapses*. The influence of the explorations of the bladder upon the economy are said by M. Civiale to be exaggerated, and that they are not worse when made with lithotrity instruments than with the ordinary sound. He denies that the preliminary examination renders the operation of lithotomy, if eventually necessary, at all more dangerous. Of twenty-eight of his patients operated upon under these circumstances, nineteen were cured and nine died; while of seventy-three cases operated upon in the hospitals under other circumstances, twenty-five died. M. Civiale also stated that, in the cases of Souberbielle, of eleven operated upon after the passage of lithotrity instruments, ten were cured.

Respecting the relapses, he endeavours to prove that the reproduction of stone is more frequent after lithotomy than after lithotrity. To shew this, he states that eighty-eight cases of lithotomy exhibited nine relapses, while out of 244 cases of lithotrity fourteen only recurred. He explains the fact by supposing that lithotomists pay less attention to the state of the bladder subsequent to the operation, than those do who perform lithotrity; and that as the secondary stones are generally phosphatic, their formation may be determined by the inflammation of the bladder, &c, thus neglected.

M. Civiale was replied to more particularly by M.M. Blandin and Velpeau, both of whom insisted upon the danger which frequently follows the explorations of lithotrity, more especially when, as was often the case, lithotomy was eventually resorted to.

M. Roux, who took part in the debate, was somewhat discursive in his remarks, alluding to the comparative merits of the perineal and the oblique section, the frequency and causes of stone among the children of the poor, &c. He stated it as his conviction, that in children lithotomy should be the rule and lithotrity the exception. In a subsequent part of his discourse, he exhibited the results of his stone operations in private practice. Of these, 54 in number, 6 were in children under ten years, in whom all were successful; 48 were in subjects above that age,—37 cures, 11 deaths. It follows, therefore, that the total mortality was 11 in 54 or 1 in 5. The contra-indications to lithotrity in his opinion, may be thus laid down. 1. In children under ten without exception. 2. When the stone exceeds a certain volume. 3. When there are several large stones. 4. When the stone is very hard. 5. When there is great irritability of the bladder.

The opinions of M. Roux were in the next place strongly opposed by M. Segalas, who maintained that children, so far from being bad subjects for lithotrity, were in reality the best; he denied also that hardness of the stone was a forcible objection to the operation.

Dr. Guerineau read a case of aneurism of the palmar arch, cured by electro-puncture.

M. Christophe introduced a new stethoscopic sign intermediate between bronchophony and ægophony, to which he gave the name *ægony*. The sound is said to be a short tremulous tone, elicited by the voice, and is considered to be indicative of effusion.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DES SCIENCES, PARIS.

NEW MODE OF RESTORING THE LIPS.

M. Sedillot, of Strasbourg, introduced a new method of *cheiloplasty*, which he had devised to remedy the deformity caused by extensive cancerous ulceration. The object of his operation was chiefly to supply the defect with integument, which from the freedom of its circulation should not be inclined to sphacelate. This he accomplished by dissecting a square portion from each cheek, and uniting them in the centre. The result was very satisfactory.

ACTION OF LIGHT ON THE IRIS.

M. Brown Seguard communicated his researches on the action of light upon the iris, in the different classes of vertebrate animals. He found that light causes the immediate action of the nervous and muscular fibres of the iris in batrachians and fish. If the eye of an eel or frog be removed and exposed to the action of the light, the pupil is seen to contract, and again to expand when the light is removed. When the light falls only upon the retina, the iris remains immoveable; in the living eye of the same animals the iris acts both by the infringement of light upon itself, and also by its action upon the retina. The pupil of a mammal or a bird, extracted from the orbit, contracts and dilates according to the degree of temperature.

M. Hamont exhibited the injurious effects of allowing public slaughter houses to be conducted in the immediate neighbourhood of dwelling houses.

THE NATIONAL INSTITUTE OF MEDICINE, SURGERY, AND MIDWIFERY.

Memorial to Sir George Grey.

To the Right Honourable Sir George Grey, Bart., Her Majesty's Principal Secretary of State for the Home Department.

The Memorial of the President, Vice-Presidents, and Council of the National Institute of Medicine, Surgery, and Midwifery—

Sheweth:—

"That your memorialists were duly elected the representative Council of the National Institute, in August, 1847, and that they represent the opinions of above four thousand of the General Practitioners of England and Wales.

"That upon a former occasion, the previous Council of the National Institute had the honor of presenting a memorial, bearing date December 24, 1846, to Her Majesty's Principal Secretary of State for the Home Department, in which memorial, the opinions and sentiments of the class of medical practitioners whom your memorialists represent were carefully and deliberately stated. That the statements contained in the memorial were subsequently explained and confirmed by a deputation from the said Council of the Institute, in an interview with the Right Honorable Sir George Grey, Bart., at the Home Office, on Friday, February the 5th, 1847, and your memorialists fully believe that at that interview, the deputation were enabled so far to convince the Right Honorable the Secretary of State of their truth and importance, as to elicit the assurance that the Council should be admitted concurrent parties to any measure of Medical Reform that may be adopted by the Government.

"That your memorialists fully concur in the propriety of the recommendation conveyed to them, and to others of their medical brethren from the same influential quarter, to the effect, that it would be desirable that the members of the medical profession should themselves meet and agree upon some general plan prior to the Government undertaking to introduce a bill before Parliament for the revision of the laws affecting the medical profession. That your memorialists have ever been most anxious to promote the views contained in that recommendation, and have been willing and prepared to meet any authorized parties representing the existing medical institutions, and to discuss any plan that might be submitted in the most amicable spirit, and with the most sincere desire to obtain such a settlement of this highly important question, as may conduce to the public welfare and the peace and tranquility of the profession.

"That your memorialists deeply regret that the advice alluded to has not been acted upon, and that the benevolent intentions of the Government have not been reciprocated in those quarters from whence an immediate proposition for a conference should have emanated.

"That your memorialists are fully persuaded that daily increasing evils press upon the people of these realms in consequence of the laws by which the Medical Institutions of the country are governed, having been found by experience to be quite inadequate to the wants of the public, and from their charters having become in a great degree obsolete. That before any efficient measure affecting the public health, or sanitary improvement can be successfully carried into effect, medical reform appears to be an essential preliminary step; and your memorialists can never too strongly impress upon the Government and the Legislature, that the medical question is quite as important to the community as it is to the medical profession itself.

"That in the opinion of your memorialists the only way to arrive at a satisfactory settlement of the affairs of the medical profession, will be in the first instance, to incorporate by Royal Charter the general practitioners in a College of Medicine, Surgery, and Midwifery.

"That your memorialists respectfully beg it to be borne in mind that the general practitioners constitute at least nine-tenths of the medical profession; that the duties which devolve upon them are of vital importance to the public, and that no act of the Legislature or the Corporations can prevent by far the largest portion of the public from being entrusted to their exclusive professional care. That the attainments of the present race of general practitioners are of the highest order, and are highly honorable to the profession; but that their position is most grievous and anomalous from being excluded from the benefits and respectability of a legal incorporation.

"That your memorialists entertain a confident hope that they have succeeded in convincing the Right Honorable the Secretary of State, of the just claims of the highly meritorious body they represent, to a legally recognized position; and your memorialists fully trust that those arguments which were found successful with a former Government, and which were so far acted upon as to have induced a former Secretary of State to state in his place in Parliament his intention to incorporate by Royal Charter the general practitioners, may have lost none of their force, or be less conclusive than formerly of the justice of their claims, and of the paramount necessity of this preliminary measure being forthwith adopted.

"That, in conclusion, your memorialists beg respectfully, yet most emphatically, to reiterate their grave and deliberate opinion, that it would tend materially to the advancement of science, to the welfare of the community, and to the best interests of the medical profession, if the prayer of this memorial were graciously acceded to, by which the general practitioners would be duly recognized; and by a properly defined title be placed amongst the medical institutions of this enlightened country.

"(Signed),

"R. R. PENNINGTON, President.

"4, Hanover Square, Dec. 8th, 1847."

BIOGRAPHICAL NOTICE OF THE LATE ALFRED HARDWICK, M.D.

[We are indebted for the following notice of our late associate, Dr. Hardwick, of Kensington, to an esteemed member of the Association.]

On Friday, the 8th of October, 1847, after a lingering illness of several months' duration, died, Alfred Hardwick,

M.D., aged 59. Having been educated to the medical profession, he settled as a general practitioner at Epsom, where he continued to practise for several years with a high reputation and great success. He married a daughter of Captain Dundee, then residing at North Cheam. This happy alliance ended in Mrs. Hardwick's confinement, when he had the great, and at that time apparently irreparable, misfortune of losing both wife and child. This affliction was so keenly felt, that he was induced to relinquish practice; and to leave Epsom, in the hope that by foreign travel his highly sensitive mind might recover its tranquillity. In this hope he made the tour of France and Italy, with parts of Germany, Belgium, and Holland. Returning for a short period, he resumed his peregrinations, and travelled through the same countries by different routes, thus bringing objects of interest in natural scenery, in history, and in the fine arts, under his attention; which, by his previously cultivated and elegant mind, he was well qualified to appreciate and enjoy.

After this second continental tour, he went to Scotland, with the intention to graduate in medicine, taking his degree of M.D., at Glasgow, in 1832. For a time he fixed his residence in London, but without any view to medical practice: and marrying a second time, to Miss Charlotte Tatchell, of Paris, he finally took up his abode at Kensington, where he continued to reside during the remainder of his life, highly respected and beloved by all who had the pleasure of his acquaintance, and rendering essential services to the various parochial and local charities and institutions.

More than thirty years ago Dr. Hardwick assisted in the establishment of the Surrey Benevolent Medical Society, promoting to the utmost of his power the successful prosecution of its objects, and after he left practice, he attended the meetings whenever he possibly could. He was also a member of the Provincial Medical and Surgical Association. As one of the Council he took an active part in the proceedings, whenever he could be present at the annual meetings; and was one of the Committee appointed to prepare a plan for schools for the sons of medical men, with the view to afford them a first-rate classical and liberal education, whether they might be intended for the medical, or for any other profession, at a very moderate expense. To this subject Dr. Hardwick devoted much time and thought. The prospectus of this plan was issued by the Committee; but it not being duly responded to by the profession at that time, the scheme may be considered to be postponed for the present, but not, it is to be hoped, entirely abandoned.

When the subject of medical reform became a prominent feature in the profession, Dr. Hardwick took it up; and after due investigation, found himself compelled conscienciously and warmly to espouse the cause of the general practitioner. He felt assured of the important truth, that in a wise medical legislation for the rectification of the evils, of which the general practitioner had so justly to complain, it ought to be borne in mind, that the welfare of the whole population of the country as respects the invaluable blessing of health, and the real interests, usefulness, and respectability of those who are the medical advisers in ordinary of the great majority of the public, are identical; that the general practitioners are not only the medical attendants in ordinary of most of the higher and middle classes of society, and exclusively of the labouring classes, but also that a large majority of the medical appointments to public offices in the provinces are held by them, and that the entire medical staff of Her Majesty's army and navy are also, in the most complete and comprehensive sense, general practitioners; that therefore the standard of education and of qualification should be high, so as to render the general practitioner fully competent to treat all the extraordinary, as well as the ordinary emergencies of medical and surgical practice.

Taking the prominent part he did, Dr. Hardwick was elected, first of all, one of the Committee of the National Association; and since then, one of the Council of the Institute of Medicine, Surgery, and Midwifery, attending the sittings of that body with the greatest punctuality, until the state of his health rendered any further attendance at the meetings impossible. He saw and felt the great importance of the principles on which the Institute is founded; their truth and their value to the great body of the profession, as also to the health and well-being of the public at large. He was, at the same time, equally assured that the incorporation of the general practitioners, by Royal Charter, as a measure preliminary to other and more extended medical reform, was most desirable; and among the last of his thoughts and wishes as respects this world's affairs, his prayers were in favour of the success of the Institute.

His urbanity of manners and elegant and accomplished mind rendered his social intercourse most gratifying to all who had opportunities of enjoying his company and conversation. And his co-operation in those public undertakings, in which he took a part, merited the esteem and gratitude of those of his friends who acted with him.

General Retrospect.

ANATOMY.

NERVES OF BONE.

M. Gros has obtained some interesting particulars regarding the distribution of nerves to the long bones. Taking the femur of the horse as sufficiently typical of the ordinary plan, he finds at least three nerves to approach the nutrient foramen,—two of them in company with the branch of the femoral artery, called by M. Gros "diaphysial," and the third, occasionally double, by piercing the vastus internus muscle. All of these are branches of the crural nerve, but there is in man, it seems, a branch of the sciatic in addition. Arrived at the nutrient foramen, the nerves are disposed differently in some subjects, but commonly a ganglion is developed, which receives the nervous branch which came through the muscle at one end, and one of the satellites of the artery at an interval. One portion of the ganglion is somewhat distinct, and is situated within the foramen; it gives two branches which receive the other arterial satellite, (which is distinct from the ganglion,) and then penetrates the medullary canal. The rest of the ganglion lies beneath the periosteal artery, which it is to be noted is a branch

of the diaphysial, whose other branch is medullary, and supplies two satellite nerves to it. Variety occurs in the ganglion as to situation, it being near to or more remote from the foramen, and as to form, it being occasionally double. The branches, both medullary and periosteal, follow, and ramify with the arteries, forming a network correspondent to the vascular, and the purpose of the ganglia appears to be to assemble, previous to this distribution, the nerves from several sources.—*Archives Gén. de Médecine.*

PHYSIOLOGY.

THE OPTIC THALAMI.

In a series of experiments upon rabbits, made after the publication of his essay "De vi motoria baseos encephali," Dr. Schriff observed the following consequences of injury to the optic thalami, &c. 1st. The lower parts of the optic thalami, and the whole thickness of the crura cerebri are slightly sensitive. 2nd. If one thalamus or one crus cerebri be destroyed, a rotation around the transverse axis of the body takes place. This movement is not due to a hemiplegia of the opposite side, for it takes place even when the action of one of the extremities of the injured side is prevented. 3rd. The injury of any part of the hemisphere above the thalamus produces no such rolling movement. 4th. The change from the rotatory movement to the rolling movement is observed only when, in consequence of the operation, the lateral part of the pons is compressed. 5th. The rotatory movement depends on a deviation of the two forefeet towards the side opposite to the direction of the rotation, combined with a movement of the neck *towards* the direction of rotation. 6th. These deviations occur only in movements effected through the brain, they are never spasmodic. 7th. The anterior three-fourths of each thalamus unite in themselves the elements for the flexion of the body to the opposite side. When the portion of the thalamus included within this anterior portion is destroyed, the rotatory movement towards the injured side ensues in the way described above. 8th. But if the posterior fourth of a thalamus, or if a crus cerebri be destroyed, the deviation of the feet and of the neck will have the opposite direction, and the movement will be towards the side opposite the injured thalamus, in just the same manner as when the anterior part of the other thalamus is injured. 9th. There appears therefore to be a decussation of the fibres in relation with these movements, between the thalamus and the crus cerebri, which decussation probably takes place in a part lying above and behind the corpora albicantia, and reckoned as belonging to the substantia perforata media. 10th. The destruction of no azygos part of the brain above or before this portion of the middle line produces any paralysis of the extremities; but the median division of the floor of the fourth ventricle produces excitement of motion. 11th. If, in dividing the crus cerebri, the pons be injured, a partial paralysis of the hind foot, on the side opposite the injury, is added to the other deviations; and the movement takes the form of a rotation around the paralysed foot, the whole body moving as the radius. 12th. Immediately after the destruction of an optic thalamus, or a crus cerebri, a few rotations are made *towards* the injured side—the effect, probably, of the irritation—they soon give place to the ruling movement. 13th. The part, irritation of which makes rabbits snarl and dogs howl, is anterior to the thalamus, in the neighbourhood of the anterior crura of the fornix. 14th. The rotation takes place in animals blinded by the removal of the humours of the eyes.—*Schmidt. Jahrb. Heft.*, 7, 1847.

PATHOLOGY & PRACTICAL MEDICINE.

ON OSSIFICATION OF THE CARTILAGES OF THE LARYNX.

The following *resumé* embraces the chief points contained in a paper upon the above subject, by M. Segond:—

1. The epoch of life at which ossification of the laryngeal cartilages commences is variable.

2. When this change takes place, it commences constantly at particular points, which for the most part correspond to the insertions of the laryngeal muscles.

3. Ossification commences in the cricoid cartilages, and terminates with the arytenoid.

4. When the cricoid cartilage is entirely ossified, its form becomes altered, so that the anterior part of the cartilage cannot move under the thyroid cartilage, whence it happens that persons in whom the change has occurred, cannot utter the high notes of the voice.

5. The thyroid cartilage when ossified undergoes a notable transformation; the groove which is commonly seen in front of the superior tubercle is obliterated, and the inferior border of the cartilage is thickened, and interferes with the motions of the cricoid.

6. There is a change, independent of ossification, which may embarrass the movements of the cricoid cartilage,—viz., a prolongation of the inferior cornu of the thyroid.

7. Two portions of the arytenoid cartilages resist the process of ossification for a long period, these are the superior internal apophyses. The *corpora triticia*, when ossified, become amalgamated with the great cornu of the thyroid cartilage.—*Archives Générales*, Nov., 1847.

CONNECTION OF RHEUMATISM WITH CHOREA.

Mr. Peacock, of Darlington, records three cases of this complication, under the impression that he is advancing a novel observation. Without referring to the oft repeated connection of chorea with pericarditis, and of this latter disease again with rheumatism, which to our minds is much the same thing as noticing the immediate connection of chorea and rheumatism, we may remind him that the direct relationship of the two diseases has within the last few months been insisted upon by Dr. Begbie, (*Monthly Journal*, April, 1847.) Mr. Peacock's cases are as follows:—

The first case I have to mention is that of a girl, aged 12. When called in, the symptoms were simply those of febrile excitement, for which saline purgatives were given two days successively. On the third day there was decided chorea, with slight fever. I gave her a mixture, with Fowler's arsenical solution and Tinctura Opii, (three drops of the first and five of the latter for a dose,) every six hours. This she took regularly for two days; on the third day the chorea subsided, and well-marked rheumatic symptoms, swelling and pain of the joints, and increase of fever, came on. She had

then Dover's powder in sudorific doses every four hours, with occasional purges. In a week from that time the pain had nearly left her, and she soon recovered without any relapse.

Case 2.—A girl, about nine years of age. On March 7th, 1846, feverish symptoms, for which calomel purges and saline mixture, with Vin. Antim., were given. 8th, ditto. 9th, every symptom of acute rheumatism. Dover's powder, with a mixture containing Vin. Colchici, to the 26th, when the rheumatism subsided, and chorea immediately supervened. For this, pills, with bismuth and an arsenical mixture, to the 8th of April, when the chorea began to abate. Quinine was then given to April 14th, when, the chorea having disappeared, the rheumatism in a subacute form again came on; the joints swollen and very painful, but not much fever. The quinine was continued, and Dover's powder, twice or three times a day, added to the treatment. This was pursued without change to May 13th, when palpitation of the heart, soon followed by œdema of the extremities, became the prominent symptom, for which diuretics in various forms were given, but without effect, and the case was eventually removed from under my observation apparently in a hopeless condition.

Case 3.—I did not see this at the commencement: the subject was a farmer's boy, aged 14. From the account which his friends gave, it appears he had had acute rheumatism about two months before; it had now passed into the chronic form; there was no fever, but great pain in the joints, especially the ankles, which were not swollen; general debility, want of sleep, &c. A mixture with hydriodate of potash, and ten grains of Dover's powder at bed-time, gave immediate relief, and was continued for some weeks, when a a very urgent message came for me to visit him; he was some miles distant, and I was unable to attend immediately. On my arrival I found the boy's friends and neighbours in great alarm and perplexity about him, he having been, as they said, quite suddenly attacked in a most strange way, and, as it appeared to them, he was "going out of his head." On entering the house I found him in the most complete state of chorea I ever saw, both sides being apparently equally affected; he had an anxious and frightened expression, and gave short and confused answers. This, with the strange antics which the disease occasioned, had, no doubt, impressed the good people with the idea that he was deranged. I ordered him a pretty strong arsenical mixture every six hours, with a dose of calomel and opium at bed-time. On the following day I was glad to find the violence of the chorea had almost immediately subsided after beginning with the medicine. The disease, however, continued very obstinate, and had to be treated with arsenic and sometimes quinine for upwards of two months.—*Medical Times*, Nov. 27, 1847.

COLD APPLICATIONS, WITH OPIUM AND QUININE, IN ACUTE RHEUMATISM.

In a case of acute rheumatism, complicated with nodes on the shins, and syphilis, an ineffectual attempt to obtain the specific effects of mercury had been made in the commencement of the case. When in health the patient weighed 220 pounds. He had been confined to bed four months, and when admitted was unable to bend the knee, wrist, elbow, or finger-joints, without great pain. Cold water dressings were kept constantly applied to the painful joints, half diet was allowed, and he took at bed-time, every night, two pills, composed of four grains of opium, and four grains of sulphate of quinine. On the tenth day of treatment he left his bed. His weight was 136 pounds. At the expiration of twenty days the pain had disappeared; the quinine and opium were discontinued. There still remained thickening and stiffness about the joints. For this condition phosphoric acid in syrup of Prunus Virginiana was prescribed, as follows:—R. Sol. Acid. Phosphorici, dr. ij.; Syrup. Pruni Virg., q. s. ut. ft. oz. viij. M. Capt. oz. ss. in Aq. Font., oz. iv., quarta quaq. hora. Under this treatment the functions of the joints were perfectly restored, and the patient gained twenty pounds in weight in thirty days, and the nodes disappeared.

While taking the quinine and opium, the bowels, which had been previously constipated, were regularly moved once in twenty-four hours; but under the use of phosphoric acid, it was found necessary to occasionally prescribe castor oil and an anodyne at night.

Dr. Ruschenberger, of the U.S. Navy, who reports the case, has been in the habit of treating acute rheumatism, upwards of two years, by cold applications to the hot and swollen joints, and administering at night from three to six grains of opium, with an equal quantity of sulphate of quinine, regulating the quantity by the condition of the pupil alone. With a dilated pupil, he found patients to bear the largest dose without inconvenience, and he has not yet met a single case in which pain was not completely removed in from twenty-four to thirty-six hours, provided the attack were recent, or of not more than a week's duration. Large doses of opium, especially in combination with sulphate of quinine, do not tend to constipate, but rather to relax the bowels. After the pain is removed by the opium, he then resorts to the use of the iodide of potassium, in medium doses, say from five, increased gradually to ten grains, three or four times daily.

Passed Assistant-Surgeon S. Holmes, who witnessed the results of this practice in his hands, has made trial of it on the coast of Africa, and with entire satisfaction. —*Amer. Journ. Med. Sciences*, July.

REMEDIES FOR INCONTINENCE OF URINE.

1. Benzoic acid has been employed with success against this complaint; it is given in doses of twelve grains daily, half in the morning and half in the evening, and this dose may even be doubled. M. de Fraene, of Brussels, records a successful case in a girl between 13 and 14 years of age, who was attacked with nocturnal incontinence, after recovering from a second attack of acute rheumatism. The complaint was neglected for several months; there was no pain in the part, the appetite was good, and the bowels regular, but the face was pale. Various remedies were employed without success, after which, two drachms of benzoic acid were made into forty pills, four of which were taken night and morning, and the complaint was completely cured.

2. A woman, aged about forty years, was received into the Hôtel-Dieu, under M. Guerard, to be treated for

incontinence of urine and pulmonary emphysema. The first infirmity appeared to depend upon a phlogosis of the neck of the bladder. The urine passed involuntarily both night and day. The asthma was treated with acetate of ammonia. The emphysema was much ameliorated, the respiration became more easy, and the asthmatic attacks after a few days ceased. The incontinence of urine, however, continued, for which enemata were ordered, containing four grains of camphor dissolved in yolk of egg, and mixed in a little water, so that it might be retained in the rectum. This treatment alone sufficed to remove the incontinence for some time. In a few weeks, however, it returned, and was once more removed in the same manner. At present the enemata are continued as a prophylactic, the cure seems to be permanent.

RAPID MODE OF PRODUCING VESICATION.

Apply six drops of a mixture of one drachm of Liq. Ammoniæ Fortissimus, and two drachms of olive oil, to the woollen side of Markwick's spongio-piline, and press this gently against the skin. In the course of ten minutes a perfect blister is formed.—*Pharm. Journ.* Feb., 1847,

SURGERY.

TREATMENT OF UNUNITED FRACTURES.

Mr. Rynd, after alluding to the practices invariably adopted in the above cases, such as friction of the ununited fragments, cutting down and removing the extremities of the bones, and passing a seton between them, as recommended by Dr. Physick, of New York, suggests a modification of the latter, as exhibited in the following cases:—

1. Eliza Kavanagh, had fracture of both bones of the leg five inches above the ankle joint. Splints applied, but bony union not obtained. After eleven weeks, Mr. Rynd introduced a seton in the following manner:—A curved needle was passed into the inside of the leg opposite the fracture, through the integuments, so deeply as nearly to touch the posterior internal edge of the tibia; it was then directed in a semicircular course anteriorly, over and close to the permanent extremities of the fractured bones, and was brought out on the outside of the limb, so that the fracture lay between the parts of its entrance and exit; it did not touch or pass between the fractured extremities. Perfect rest was enjoined, and on the 21st day union was established.

2. John Reilly, aged 30, had ununited fracture of the left humerus, immediately above the condyles; fragments moveable, and produce pain by pressure on the brachial nerves, when the cervix is raised. On the 10th a seton was introduced with the same precaution as in the former case. The arm was released from the splints somewhat too soon, but the union was ultimately perfect.

3. William Archer, aged 13, had oblique fracture of the femur fifteen months since; motion perfect between the fragments, but no grating, shewing that there is ligamentous union. The boy is of a scrofulous habit. On the 14th, a seton was introduced posteriorly to the bones, and brought out in front. Dessault's apparatus was applied, and perfect rest enjoined. The seton was removed on the 28th. In a month's time the fractured portion appeared to be firm, and in another week the boy walked without a crutch.—*Dublin Quartely Journal*, 1847.

NEW METHOD OF APPLYING LIGATURES TO TUMOURS.

Professor Fergusson and Mr. Walne have both described this method. It consists in passing a double ligature through the base of the tumour, and then dividing it; a needle with the eye to the point is then threaded with one *tail* of the ligature, and passed also through the base of the tumour at right angles to the double thread; this tail is withdrawn from the needle, and the eye threaded with the other *tail* of the double ligature; the needle is then drawn backwards, bringing with it the second ligature, which then passes at right angles to the original double ligature, and through the same channel as the first tail. The end of the ligatures having been left long enough for tying, there are now two ligatures, forming two figures of 8, each embracing two opposite segments of the tumour, and the surgeon has only to tye the ends of each ligature once, in order to command the base of the tumour.—*Medical Gazette.*

NEW METHOD OF REDUCING HERNIA OF THE IRIS.

This consists simply in cauterizing a spot, at a distance from the hernia, with nitrate of silver; it is based on the following data:—1. Hernia of the iris through the cornea does not become disorganized for some days. 2. The protruded iris, irritated by the contact of the tears or the air, or by the friction of the superior eyelid, or even of the edges of the ulcerated cornea in which it is imprisoned, has a tendency to swell, and the irritation and swelling prevent mortification and *arrest cicatrization.* The progressive engagements of the iris is proved by observation: if a recent hernia be touched with an irritating body, it instantly acquires three times its original size; and if we watch the progress of cicatrization in the ulcer of the cornea, the hernia being unreduced, the pupil is found to diminish by degrees, and even to disappear. 3. Adhesions are established between the iris and the cornea before the iris is disorganized; for a few days these are very weak, and may be destroyed at once *by augmenting the vascular action of the parts which furnish them,* or by a new inflammation developing itself in another part of the eye. 4. The materials of adhesion are in the first instance furnished by the cornea; the cornea is in a morbid state at the point at which the healthy iris protrudes. 5. These materials are derived from the divided vessels of the ulcer, the origin or base of these vessels being at the circumference of the cornea. 6. By irritating the part in which the base of these vessels ramify the secretion at the edges of the ulceration is augmented; in this way a fluid secretion may be induced around the hernia, which will destroy the imperfect adhesions, and give freedom to the iris in the ulcer, which latter is augmented in size by the secretion. 7. By putting the iris under the influence of belladonna before producing such an irritation mechanically, we obtain a power, placed behind the cornea, acting from

before in a direction backwards, and capable of reducing the hernia.

After this beautiful chain of pathological reasoning Desmarres states:—A portion of the iris having projected through an ulcer of the cornea, and instillations of belladonna having been used for some days without any beneficial result, it may be inferred that the pupil has been rendered as large as possible by this agent, the operator proceeds thus:—

The upper eyelid being held by an assistant, and the lower eyelid depressed with the index finger of the left hand, he applies with the right hand the point of a pencil of nitrate of silver to the conjunctiva of the bulb, close to the cornea, and cauterizes it in three or four points as energetically as possible, without penetrating the mucous membrane too deeply. A very active irritation of the vessels which feed the ulceration of the cornea is thus provoked, and the secretion necessary to set the iris free is the result. Sometimes, instead of points, a line of cauterization is made in the neighbourhood of the hernia, and in some instances, where the first cauterization has failed, after an interval of two or three days, a second, third, or fourth even, on the cornea, but taking the greatest care that the caustic does not extend to the iris, otherwise the hernia would at once be increased. In a rare instance success was not obtained until after the eighth application; but the reduction is generally effected after the first, second, or third. Desmarres has succeeded in so many instances by this method, that he has ceased to count the operations.—*Mr. Ancell's Report on Ophthalmic Surgery, Half-Yearly Abstract*, Vol. VI.

RICORD'S OPERATION FOR PHIMOSIS.

His method is as follows:—The penis is allowed to remain in its natural position, and no traction is used: a circular mark is made with ink upon the prepuce, about two lines anterior to the base of the glans, and parallel to the corona: a long and strong needle, its point covered with a wax head, is then introduced between the glans and prepuce, and made to pierce the whole thickness of the latter, on the mesial line, and a little in front of the circular mark. The mucous membrane and skin of the prepuce are thus fixed, and the needle is allowed to remain. Behind it, and in a longitudinal direction, a fenestrated forceps, with notched edges, is then firmly applied. The fenestræ of the instrument correspond to the circular mark and the glans; at this stage of the operation the latter is to be pushed backwards. The next step is to pass sutures, five or six in number, through the fenestræ; and when all the threads are applied, the prepuce is shaved off with a bistoury made to glide between the needle and forceps. The latter is then withdrawn carefully, so as not to disturb the ligatures. The assistant should be desired to press the forceps very tightly when the prepuce is being shaved off; if this be neglected, the prepuce will yield, and the sutures will be cut. When the forceps is removed, the arteries which are noticed to bleed, should be tied or subjected to torsion; the threads which pass above and below the glans are then divided in their centre, and the respective ends of each half resulting from this section are tied, to bring the mucous membrane in contact with the skin. Of course there will be twice as many sutures as there were threads passed.

Treatment.—We should, after this operation, enforce rest, low diet, aspersions of cold water, and camphorated pills; union by first intention rarely takes place completely. The submucous cellular tissue will generally be found infiltrated with serosity on the next day, but it is gradually re-absorbed. The sutures ought to be removed on the fourth day; they might, if left longer, lacerate the tissues. The parts are usually healed up by the tenth or fifteenth day, excepting in those cases where the union by first intention takes place as early as the fourth or fifth.—*Lancet*, November 27. 1847.

MANCHESTER MEDICO-ETHICAL ASSOCIATION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I wish to make known to the profession, through the columns of your Journal, that the Committee of the Medico-Ethical Association are desirous of eliciting the current opinion of the profession on the merits of their bye-laws, and will be happy to acknowledge the favour of any suggestion or critical remarks that may assist in carrying out the objects of the Association. At the same time I beg to intimate that all communcations, whether in the nature of suggestions, corrections, or complaints, must be authenticated by the signature of the author. In future, therefore, anonymous communications cannot be responded to.

Your correspondent, H. B. B., either misapprehends the purport of the rules of which he complains, or by having, on his own admission, systematically violated the principles therein contained, throughout his professional career, and to which he vauntingly attributes his success, cannot be competent to judge impartially of the propriety of such rules.

Further than this, the practitioner, who for a series of years has, "in no instance," acted as an "officiating friend," can scarcely be qualified, from the relative position he holds towards his professional neighbours, to criticise rules of medical etiquette.

The Medico-Ethical Association has for its object the moral social elevation of the profession.

I am, Sir, yours respectfully,

RICHARD ALLEN,
Hon. Sec.

112, Oxford Road,
Manchester.

THE METROPOLITAN GRAVE-YARDS.

Accurate returns have been made of the superficial extent of the parochial and some other burial-grounds of the Metropolis, and of the numbers of bodies annually interred in each. The *annual* average number of burials per acre, for the seven descriptions of burying-places comprised in the intra-mural grounds, is stated by these official returns to be 2,271. Now, if we divide this by 7, we have the average for each, which gives 324 burials annually to the acre. From

the total, we may fairly abstract the burial-places of the Jews, and those of the Society of Friends, which are well conducted. This will give us five species of grounds, with an annual average of 2,130 burials to the acre, or an average of 426 for each. The proper number, you will remember, is 136 to the acre; in Germany, the average is only 110 burials per acre per annum. Thus, at the first glance, it is evident that our parish grave-yards are made to receive every year three times as many bodies as they ought, and four times as many as are permitted by the laws of well-regulated Continental states. The inevitable crowding of our grave-yards may be illustrated in another way. The annual mortality of the Metropolis, at a low computation, is 50,000. Now, supposing the burials to be renewed every ten years, (and this is the shortest period that should be allowed for the decomposition of the human body), 444 acres would be required, whereas we have only 209. But this is not all. There are 182 parochial grave-yards in London. Of these, only 48 are confined within the proper limit of 136 burials to the acre; the rest exhibit various degrees of saturation, from 200 up to 3,000 per acre *annually*. This is scarcely credible, but official returns confirm the truth of what I assert. In very many the annual average per acre exceeds 1,000.—*From Mr. G. A. Walker's Fourth Lecture on the Metropolitan Grave-Yards.*

USE OF CHLOROFORM.

A correspondent suggests the following queries on the use of this agent, to which he requests replies from gentlemen who have had practical experience of its effects :—

What is the best time for administering the chloroform in obstetric cases?

For how long a time may a patient be kept with safety under its influence?

At how early an age may it be administered for surgical purposes?

Medical Intelligence.

PROGRESS OF THE CHOLERA.

It is stated in the Union Médicale that the cholera has crossed the frontiers of Prussia, and made its appearance at Tilsit. The symptoms are, however, reported to be mild, and the occurrence of the disease altogether in this quarter seems to be of very questionable authority.

APPOINTMENTS.

James Syme, Esq., Regius Professor of Clinical Surgery in the University of Edinburgh, has been appointed Professor of Clinical Surgery at University College, London, in the room of Mr. Liston, deceased.

James Moncrieff Arnott, Esq., has been elected Examiner at the Royal College of Surgeons, in the room of Mr. Liston, deceased.

George Sayle, Esq., has been elected Surgeon to the West Norfolk and Lynn Hosptial, in the room of Mr. Whiting, resigned.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, December 23rd, 1847:—Frederick George Harcourt, Ipswich; Peter Knight; Augustus Grant, London; Osbert Fishlake Cundy, London; Benjamin Button, Hopton, Suffolk; Robert Stead Jones Stevens, Ely.

OBITUARY.

Died, December 18th, 1847, Abraham Jubb, Esq., F.R.C.S., Senior Surgeon to the Halifax Infirmary, and Member of the Council of the Provincial Medical and Surgical Association.

December 20th, at Mountmellick, of fever, Thomas Hipwell, Esq., Surgeon.

December 21st, at Douglas, Isle of Man, aged 56, Edward Smith Graham, M.D., late Surgeon of the 4th Light Dragoons.

December 21st, Edward Walker Esq., Surgeon, Kington.

December 23rd aged 56, Thomas Pitt, Esq., Surgeon, Walsall.

December 24th, of fever, Charles Donellan, M.D., Medical Attendant to the Armadown Dispensary.

December 25th, of fever, Francis Bodkin, Esq., Apothecary to the Clifden Poor House.

December 25th, aged 47, Frederick H. Parker, Esq., Surgeon, of Portugal-street, Grosvenor-square.

December 26th, at Pangbourn, Berks, from diseased lungs, James Craig Somerville, M.D., late Anatomical Inspector for England and Scotland, aged 48 years.

December 27th, at Oranmore, of fever, E. Lambert, M.D., F.R.C.S.I.

December 27th, aged 72, Swinton M'Leod, Esq., Deputy Inspector-General of Hospitals.

December 28th, of fever, George Seymour, M.D., Physician to the Killane Dispensary, Galway.

January 2nd, 1848, at Saint Mandé, aged 59, M. Jourdan, Member of the Académie de Médecine, Paris, and well known as the translator into French of several German works.

January 4th, at Southsea, aged 78, Benjamin Lara, M.D.

BOOKS RECEIVED.

Discourses on Medical Education, and on the Medical Profession. By John Ware, M.D., Hersey, Professor of the Theory and Practice of Physic in the University at Cambridge, (U.S.) Boston: (U.S.) 1847. 8vo. pp. 113.

Remarks on the Conduct and Duties of Young Physicians, &c. By J. Y. Simpson, M.D., Professor of Midwifery in the University of Edinburgh, &c. &c. Second Edition. Edinburgh: Machlachlan, Stewart and Co. 1848. 8vo pp. 23.

TO CORRESPONDENTS.

Communications have been received from Carshalton; the National Institute of Medicine, Surgery, and Midwifery; the Birmingham Pathological Society; Mr. S. W. Kidgell; Mr. E. Hoskins; Mr. A. Markwick.

The author of the case of Obstinate Constipation has omitted to send his name.

PROVINCIAL
MEDICAL & SURGICAL JOURNAL.

OBSERVATIONS ON THE PESTILENTIAL CHOLERA OF 1832-3.

By James Black, M.D., &c., Manchester.

As the public are under considerable alarm about the pestilential cholera revisiting this kingdom, on its progress north-westward, from Persia and Koordistan, and presuming it may not be unseasonable to review our former experience of this dreaded scourge, and, moreover, to make known to our younger brethren who have entered the profession since that period, some of the leading features of the epidemic, I have taken the liberty of sending a few observations, which I have extracted from my case book, and which were recorded at the close of each of the two years' visitation of the disease, but have never hitherto been published. In the absence of all apprehension of the epidemic being about to revisit us, such resuscitated remarks would be out of place, as they would certainly be scarcely worthy of perusal; but any contributions on this subject from contemporary practitioners who witnessed the former epidemic, will, it is thought, be not unaccepable to your Journal; and a reciprocal refurbishing and cleansing up of our old armour may better enable us to meet the enemy, if it should please Providence to permit it to come among us.

Though I have several notes of individual cases recorded at the time, I shall only extract the concluding observations which I made at the close of the two pestilential seasons, in 1832 and 1833.

PESTILENTIAL CHOLERA IN 1832.

The disease having appeared in Sunderland in October, 1831, and since diffused itself through nearly every district and town in the three kingdoms, with more or less violence, but now at this date has almost disappeared, the Central Board of Health, at London, having also ceased to publish even weekly reports, I think it useful to record a few concluding observations on the subject. My observations have been confined to what I have witnessed at the Cholera Hospitals at Liverpool and Manchester, from two days attendance, along with the cases which occurred in Great and Little Bolton, which did not exceed ninety cases in all, more than the third of which were fatal.

Observed symptoms.—In the mild cases, or the incipient stage, diarrhœa, with flatulence, but without griping; scanty or difficult urine; inappetence or nausea, or slight vomiting of inodorous or acid matters; slight confusion of intellect; dulness of the senses; constriction of the features; debility; cramps in the toes, or calves of the legs, All these symptoms were so far under the power of medicine, such as calomel and opium, external warmth, slight aperients, and astringents.

Acute seizure, or second stage.—Frequent purgings of turbid gruelly motions, followed soon by vomiting of similar fluids, the attack commencing suddenly in the night, between midnight and six in the morning generally. Severe and painful spasms soon ensued, affecting the legs and toes, more rarely the arms and fingers, extending to the abdominal muscles; vomiting at times like forcible squirtings; great thirst; cool breath; pinched and anxious countenance; skin soft, clammy, and inelastic; urine suppressed; pulse small, retiring, and vascillating, all of which symptoms soon run into the *third* or—

Asphyxiated Stage.—Pulse more feeble, easily suppressed, or gone from the wrist; breath cold; eyes muddy and suffused, expressive of fear, or sunk in their sockets, with the circle of the palpebræ of a livid, or a earthy lurid hue; features collapsed; breathing slow, sometimes heaving; posture drawn to one side, and the patient inclined to retire from notice, or stretched on the back with open mouth; tongue cold, drier, with a yellow coating; thirst great; hearing dull; hands and legs cold and shrivelled, fingers more remarkably so, and even corrugated in labouring people; nails blue; neck and breast very livid; buttocks and thighs sometimes very much so. The body had a peculiar sensation to the touch,—much resembling a dead skin stretched over a living frame, as if the vascular connection had long since ceased between them, and when or wherever the body felt warm, it appeared as if the skin acted as a condenser, and partook of no vital nor calorific communication. This condition of the surface was very peculiar and diagnostic, especially since often after death, the body acquired a renewed warmth from *physical* diffusion, which the skin failed, during life, to transmit by *vital* continuity. The heat of the corpse re-appeared in several cases from two to six hours after death, and it often continued for twenty-four hours, and in some cases much longer than it does in persons dying from

acute or phlogistic diseases. The sensation imparted by the skin to the hand, even in mild cases that recovered, as well as in the asphyxiated ones, was so diagnostic, that in my limited experience, I took it as the most characteristic symptom in determining this species of the genus cholera. Some practitioners have even said, that they felt a shock, somewhat similar to that from galvanism at the moment of touching a patient so afflicted. To resume, the urine was always suppressed; purging—of an involuntary and draining nature, except when entirely stopped; voice—a whisper, or gone. The voice was also very diagnostic in mild and recoverable cases, and sufficient to betray the impending and probably more severe attack, if not timely prevented.

Treatment.—The mild or gently incipient stage was easily and successfully treated, but the asphyxiated cases were nearly hopeless. The vomiting and purging were not so formidable to combat as the state of the circulation. In this latter stage various remedies have been used, for which the journals may be referred to, but from all that I have seen and heard, I incline to a small bleeding in stout subjects; smart doses of calomel and croton oil, repeated to the second or third time; then small doses of the former, with capsicum and camphor; non purgative saline medicines, combined with ammonia. I have seen benefit from an emetic of salt and water at the commencement, followed by small doses of Oleum Terebinthinæ or chloric æther. No opium unless there were spasms or active purging or vomiting, with heat of body. I have seen this drug tend to narcotize, and if consecutive re-action take place, the opium seems to be absorbed nearly all at once, and the brain is consequently and evidently enervated and overcome. Brandy has also the same effect in a less degree, and should be very sparingly exhibited. Enemata of hot water, salted, or with Oleum Terebinthinæ, a little chloride of lime, or with some spirits, or one entierly of hot beef tea, have been used with more or less relief. I would inject much and leave the patient to drink warm water *ad libitum*, to distend, warm, and promote circulation in the portal system, which is allowed on all hands, to be in a much congested state, besides the mere dilution of the morbid secretions of the bowels seem to do good. I am doubtful of the application of great external heat being of much avail, beyond an occasional sinapism to the epigastrium, hot bran poultices along the spine, or frictions with hot and stimulating oils, as oil of camphor, oil of succinum, oil of turpentine. I fear too much heat exhausts the small remainder of vitality in the skin and whole frame, and excites the heart to undue action on its enervated and carbonized blood. The capillary system is no longer, or at the time, under the call of such a stimulus. The vitality must be first diffused, and if the heat applied be too great, it is exhausted instead of being diffused.

Mode of Propagation.—Naturally inclined, from analogy, to the doctrine of non-contagion, I have, notwithstanding, considerately weighed my own observations, as well as those of others, and I can still see no proof of contagion strictly speaking, nor that the disease in any way follows the laws of the acknowledged contagions, as plague, small-pox, &c. Its appearance at Bolton could not be traced to importation. The first two fatal cases occurred in the detached vale at Mill Hill, along the course of a sluggish stream and mill-race. The foci or infected localities in the town were principally confined to some courts and entries, lying on the north side of Deansgate, and on the rising brow of a dirty and muddy river, whence a noxious effluvium may probably have arisen. The victims of the disease in these places were lodged in damp and thickly-confined houses, and were more or less intemperate. This peculiarity of infection along the course of the river, even through the town, was very remarkable, and accords with the general remarks of the vicinity of streams and water-courses, being more infected with the disease than other situations. The moral contagion of fear seemed, here and elsewhere, to have had a most obvious agency among the many alleged modes of propagation; and it appears, that where this depressing passion was most prevalent, the disease put on most of its reputed contagious character. In the view of its merely epidemic nature, the effects of fear,—more easily and powerfully excited from the aspect of this disease than from that of most others,—were enervated and paralysed action of the heart, remora of circulation, and consequently congestion in the large vessels, and collapse in the capillaries, would take place, and constitute the very initiatory stage of cholera. We know that several diseases of a formidable character have been propagated by moral sympathy, such as different kinds of convulsions, as epilepsy and chorea, and why not the convulsive one of cholera, as far as the spasmodic symptoms are concerned?

Autopsia.—From all I have read, heard, and in any limited inspections, observed, there seems to be no morbid lesion which constitutes the prominent autocrasy of the disease; neither can any one say, before inspection, where the most obvious changes in the internal organs and tissues will be found. The pre-existence of the malady may, however, be fairly inferred from the state of the skin, blood, contents of the stomach and intestines, the contracted state of the bladder, and the distended gall-vesicle; even if the symptoms during life had not been communicated to, or been seen by, the autopsist.

One reason why the disease visited Bolton so slightly this year seemed to be, that the constitution of the inhabitants was little prepared for, or rather fortified against, its reception, the health of the place being remarkably good—never more so since I have witnessed it for these twelve years or past—and especially from its being free from intestinal complaints. Whereas, if the cholera had visited us in 1831, I believe the disease would have committed ravages equal to those of any place in the kingdom; for common cholera and dysentery then prevailed to an extent beyond what I have ever seen to do among civilians. For an account of this epidemic, I may refer to the article on the subject in the forty-fifth volume of the *Edinburgh Medical and Surgical Journal.* While this intestinal epidemic was going through its phases with us, the malignant cholera showed tself on our eastern shores at Sunderland;

but before either the morbific current, aerial or terrestrial, or any of the pestiferous communication had reached us, we had thrown off our enfeebling shackles, and had recovered renewed strength, and gained a comparative immunity.

During all last year I observed that bleeding was much seldomer required than usual in several diseases; the general constitution was *asthenical*. During this summer and autumn it remained in a healthy equipoise, and the mental barometer kept high and elastic from political excitement and a plentiful harvest. On the commencement of this winter, however, the lancet has been much more in requisition, and patients bear bleeding well; thoracic congestions and rheumatism have prevailed, with many cases of irregular phlogosis and plenitude; while all debilitating or asthenic diseases, as diarrhœa, dysentery, and typhus, have been rare, with the few exceptions of malignant cholera.

It is now the great question, whether the cholera, having afflicted the kingdom for a year, and having now almost disappeared, it will return, or break out again in the next succeeding years, in any epidemic form, or whether the morbific current having passed over us, it will expend itself on the eastern and western coasts of America, and then return to its native Ganges, whence it has rushed over the greater part of the world? If we may hazard a conjecture, and which is consonant with my notions of its transmissible and pathogenic nature, it will appear next summer, if it be hot, in some minor shape, sporadically, and without any character of contagion. It will likewise take one or more years before the constitution loses its predisposition to it, and resumes its former strength and immunity. 20th Dec. 1832.

OBSERVATIONS ON THE DISEASE IN 1833.

In fulfilment of the fears and predictions of many medical prophets, the pestilential cholera has again made its appearance in many towns and villages of the kingdom, though in a more limited or sporadic manner. The deaths to the number attacked, were, however, proportionably greater than during last year, and the disease affected, not exclusively, the poor, desolute and intemperate. Many persons in good circumstances have been suddenly seized and carried off in the space of from six to twelve hours. Nothing new in the pathology or treatment has been brought forward, and notwithstanding the thousand nostrums and the rational empiricism of many remedies, medical men seem as much at sea as ever, as to any systematic and successful treatment. I have not heard of children being anywise affected with the disease this autumn, and those who have been the principle victims, have previously laboured under a weak state of the digestive organs, merging into slight disturbance, or diarrhœa, previous to the explosion of the disease; and this, whether arising from intemperance, or constitutional debility. All accounts describe the cases to have been unusually malignant and speedy in their fatal progress, and the consecutive fever has been little spoken of this season. The deaths in London from the disease never exceeded 260 a week. In Bolton there were in all about twenty deaths. Of these, I have detailed at length four very interesting cases, as having proved fatal to people in good circumstances, and three of them residing in a very dry and healthy situation; but I consider it quite superfluous to transcribe their cases in this place. Two of the principal circumstances recorded, are the great and increased warmth of the body after death, and the relief derived in one case, when there was no pulse at the wrist, from venesection to twelve ounces. I have also recorded the recovery of a fully formed asphyxiated case, in a stout young man, from bleeding, non-purgative salines and external warmth, but without the least particle of brandy or spirits, to which the patient had a great reluctance.

Remarks.—From what I have additionally seen this season, I consider the disease one of the most hopeless and mysterious I have ever witnessed. I can no otherwise account for the dreadful intensity of the phenomena, than by a sudden enervation, similar to the recorded effects of the upas poison on the heart, arteries, and blood. It is in the muscular or the organic life of the circulating system that the explosive phenomena take place, however much any disorders or discharges of gastric and cœliac organs may prepare the way. No extent of simple vomiting and purging could lead to such sudden annihilation of the powers of the sanguiferous system, in the absence of some superadded azootic poison or impression. Sea-sickness often produces far more retching and vomiting, and diarrhœa and dysentery are often attended with more debilitating evacuations, and in some asphyxiated cases of cholera, there is little purging or vomiting at all. These evacuations seem more the consecutive or concomitant effects of the one atonic cause, which exhibits itself in its essential and primary force on the blood and the apparatus of circulation. To me neither an excess of carbon, nor its acid, nor a deficiency of them, have any thing to do with the motive onset, nothing but a direct poisonous ferment, or a deprivation of the principle of organic life, can account for the phenomena. The sensorial powers are for a long time comparatively unimpaired; so are the animal functions; spasms plainly arise from the muscular powers, and those of the nerves losing their antagonizing balance. On this view, which is corroborated by cadaveric inspection, the heart and great vessels are loaded with devitalized blood, choking up the movements of the heart which is itself enervated. Abstraction of blood, therefore, in all full-grown subjects, or where there are much fluids, is indicated, when the blood can be solicited to flow, but this is sometimes found difficult. Opium, in this view of the disease, tends still more to enervate the muscular power, by its sedative and narcotic effects; while brandy, and all alcoholic stimuli exhaust still more the remainder of the vital and muscular energy left, though they may temporarily produce a fuller exhibition of life and motion, and enliven the sensorial functions. The indications seem to be,—to husband the muscular or organic powers, to take the load and remora from the heart and great vessels, to equalize by cautious means the circulation, to gently nourish the digestive organs, whereby a renewal of the vital forces may be effected, and if this be

accomplished in the least degree, it is the commencement of a cure, however destitute of fluids, sanguineous or others, the afflicted patient may be. Experience may correct or confirm these views.

October 15, 1833.

SHORT NOTES OF THE OPINIONS AND PRACTICE OF THE LATE JOHN PEARSON, ESQ., F.R.S., ON SYPHILITIC DISEASE.*

By W. S. Oke, M.D., Physician to the Royal South Hants Infirmary.

Treatment of Indolent Bubo.—When its progress is slow, when there is but little pain, and not much hardness, and when the skin is not discoloured, it may be stimulated with blisters, gum-plaster, electricity, and dry cupping. Dry cupping, by inducing an influx of blood into the part, will sometimes excite the action of the absorbents, and so change the character of the disease from an indolent to a phlegmonous bubo. With this view dry cupping is preferable to blisters. In hospital practice a hot iron may be drawn over the surface, so as to excite a more free and vigorous circulation, by which means indolent tumours of this kind have been considerably lessened. Along with this local treatment, a generous diet and exercise will be found beneficial.

When the structure of the gland is altered, when the integuments are diseased, and when matter has begun to form, fomentations and poultices may be tried, but the latter must be applied as hot as they can be borne, or they will be of no benefit. Poultices may also do good by pressure, especially if ecchymosis be present. Stimulating plasters, composed of Burgundy pitch, with a small quantity of cantharides or euphorbium, are also (especially the latter,) very serviceable. But if the integuments are very much diseased, it will be best to destroy them by the use of the potassa fusa, after which linseed poultices are to be applied till the slough separates and is thrown off. It ought never to be removed by the knife or scissors. After its spontaneous separation, the sore may be poulticed three or four days, till it is clean, and then treated with the red ointment,—the Unguentum Hydragyri Nitrico-Oxidi.

When one or more absorbent glands appear prominent on the granulating surface, they ought to be removed, as they act as extraneous substances. The best way of doing this is to pass a piece of lint under one or more of these by means of a probe, to produce a more perfect suppuration, and in a short time it will be easy to pluck each out from its situation. The cavity should then be filled with the "Pulvis angelicus" till the parts become healthy. [This is also called algaroth, from its inventor Victor Algarotti, a physician of Verona; also Mercurius vitæ, and Mercurius mortis. It is a metallic oxide, in the form of a white powder, and is deposited from the chloride of antimony,—butter of antimony,—when mixed with water.]

Another method of treating these glands, when very prominent, is by ligature, and after their removal, by escharotics, either by filling the cavity with a Trochiscus de Minio, [made thus:—Red oxide of lead half an ounce, bi-chloride of mercury one ounce, bread crumbs four ounces, rose water enough; the mass to be cut into oblong troches;] or by sprinkling the surface with red precipitate, as it is of great importance that the bottom of the sore should be kept clean. If the edges become callous, they must also be destroyed.

Sometimes several small glands in the vicinity suppurate, whilst the larger bubo appears inclined to heal; this may be suspected when there is a greater discharge from the ulcer than its size would account for, and by pressing on some particular part of the margins of the sore, pus will be pressed into the general cavity, and at once discover the direction of the diseased gland. Such a case will occasionally yield to poultices, but more commonly it becomes necessary to expose the sinus by rubbing caustic (the caustic alkali,) into the skin over it.

When the ulcer assumes a pale flaccid appearance, having an unequal surface, and thick jagged edges, its condition may be improved by fomentations and poultices, with warm dressings; and by bark, sarsaparilla, and wine internally. The general health will be also greatly benefitted by warm sea-bathing. The jagged edges of the sore may be removed by the knife, or by caustic, for until these are made soft, equal, and healthy, little good can be done.

When the ulcer is deep, the orifice small, and the discharge continues to be considerable, it is probable that a lymphatic has been injured; it will therefore be necessary to destroy the morbid part entirely, which may be done by pressing a piece of lunar caustic or a bit of sulphate of copper into the opening, leaving it there several minutes, and this application may be repeated, if necessary. When, however, the erosion is deep and out of sight, especially if near some important blood-vessel, such a treatment is not admissible. The potassa fusa is never to be applied to a part out of sight; indeed it ought not to be left even upon the integuments; the better way of using it will be to rub it upon the skin till it appears dead, after which a poultice may be applied. Sometimes a bubo, instead of healing after the completion of a mercurial course, will become painful and ulcerate very extensively, even to the external part of the thigh, or in a contrary direction to the scrotum and anus. The ulcer is ill conditioned, is attended with a very indifferent state of health, and often resists every mode of treatment. Sea-water poultices, solutions of white and blue vitriol, and even the actual cautery have been used locally. Bark, cicuta, the oxymuriate of

* Continued from page 10.

mercury, opium, decoctum Lusitanicum, muriate of barytes, chalybeates, compound lime water and decoction of guaiacum, together with every kind of diet, have been tried internally without any particular benefit. [The Lisbon diet drink is made thus,—sliced sarsaparilla, the root of china, of each one ounce; walnut peels dried, twenty; of antimony, two ounces; of pumice stone powdered, one ounce; distilled water, ten pints. The pumice stone and antimony are to be tied into separate pieces of linen, and boiled along with the other ingredients, till only half the fluid remains; the dose is two pints or more, per diem. This is supposed to be the genuine prescription for this drink, although there are others in some measure varying from it.] A change of application will be certainly found useful, and that mode of local treatment will be most efficacious which gives the least pain. Great attention must be paid to the general health; warm sea-bathing, good air, exercise, and a generous diet promise most success.

In other cases, where the bubo is nearly healed, it will become changed into an ill-conditioned sore with jagged and flabby edges. It is attended with a tingling sensation, and though small at first, will spread rapidly from one spine of the ilium to the other, healing in one part and ulcerating in another. It will sometimes run down the thigh to a great extent, and when it occurs on the penis, it will extend to near the arch of the pubis, destroying the integuments partially or entirely. In this case the generni health is to be mainly consulted. Mercury will do much harm; but sarsaparilla, and the muriate of barytes will be of use. At the same time the sore should be kept clean, free from irritation, and easy, by ointment made of the extract of lead, and by calomel and lime water. The cure depends upon some inexplicable change of the constitution; and when this has taken place the sore will heal in a short time.

[By the discoveries in modern science, these cases are most successfully treated by the use of the iodide of potassium, along with alterative doses of the blue pill, by which that change of constitution, above mentioned by Mr. Pearson, appears to be speedily and almost miraculously brought about.]

Scrofulous Bubo.—This kind of bubo, although derived from syphilitic poison, instead of being diminished is generally enlarged by the use of mercury, and there is not any specific remedy that will reduce it. When it is hard and indolent, blisters to the part will be of service, together with the internal adhibition of bark and soda; the tepid sea-bath at the temperature of 94° or 97°, will also be of some use.

When the swelling is composed of several small glands, and when they are not reduced by a mercurial course, the use of mercury is to be discontinued. If the glands suppurate, they form an ill conditioned sore, which heals with difficulty. Here the same mode of treatment is required as in other scrofulous ulcers. A poultice of the fresh leaves of hemlock is a good application.

Further observations on the treatment of buboes.—Sometimes a bubo becomes gangrenous early, the gangrene spreads rapidly, destroying all the integuments at the upper part of the thigh. In such perilous cases the femoral artery is sometimes eroded, and death ensues immediately; and though the artery may escape, the disease will probably prove fatal. These symptoms must be treated upon general principles, and not with mercury.

When a syphilitic bubo has been for the most part reduced, the gland or glands often remain larger and more indurated than natural. This is of little moment, especially if the gland be movable or circumscribed; wearing a piece of mercurial plaster, or of soap cerate, or rubbing a little mercurial ointment and camphor on the part, will be generally sufficient. If the patient be very anxious for the removal of the glands, they may be extirpated. Again, whenever the structure of the gland is much altered, and perfect resolution impossible,—or where it is so destroyed that only a kind of bag instead of a gland remains, it is probable that some of the syphilitic poison is retained in it, and that the disease, through its medium, may be reproduced time after time. In such a case the gland ought certainly to be removed by extirpation.

Secondary symptoms.—When mercury is not employed, or where it has been ineffectually administered, though the primary symptoms may appear to be cured, the virus is carried into the blood by the absorbents, and thus produces a new order of symptoms, affecting other parts.

In order to cause these new effects, it is not necessary that the primary should be cured, as both may exist at the same time; and a fresh chancre may be contracted whilst the secondary symptoms exist.

The virus having been received into the blood, does not long remain inactive; pains of the limbs are felt, and there is some degree of febrile disturbance. These symptoms do not always accompany the morbid development, but they generally take place; and after a few days, relief is experienced by the appearance of an eruption, or by an ulceration of one of the tonsils.

Secondary symptoms usually take place within three months of the apparent cure, or when mercury has been ineffectually employed; but should they not appear at the end of six months, the patient may consider himself secure. It is a mistaken notion that the disease can lay dormant in the system for some years.

In some respects the virus proceeds in a manner not very dissimilar to the exanthemata. In all these some peculiar extraneous matter enters into the blood-vessels, and is thrown out under different forms through the emunctories. Variola, though in some instances it is capable of reproducing the disease more than once

does not generally recur after the first development, having produced in the constitution a certain inexplicable change. In lues, on the contrary, a person may be affected with constitutional symptoms time after time. These examples are not of frequent occurrence, but the fact is certain.

Persons who have suffered from secondary symptoms are generally more cautious for a time, and if they do contract a fresh infection, they seldom delay long in applying for advice, and hence constitutional symptoms are not very often observed in the same individual a second time.

The syphilitic poison does not observe a definite course, but runs on, and would, if unchecked, destroy its victim. There are no natural powers which can so alter its great activity as to render the poison innoxious. When the poison attacks the skin or throat, a process goes on, similar to that of an abscess, and the matter may be again absorbed to aggravate the disturbance of the system.

When no mercury has been used, the symptoms, after about a fortnight, will be less severe, as if the activity of the poison were suspended; and if too small a quantity have been taken, the same symptoms will appear and disappear several times.

Amongst the first class of secondary symptoms are to be reckoned ulcers on the tonsils, uvula, and velum palati; blotches on the skin; lippitudo; ulcers on the umbilicus, on the nipple, under or between the toes, and on the penna nasi and upper lip; sarcocele, tinnitus aurium, intertrigo, rhagades, &c.

(*To be continued.*)

ON RETROFLEXION OF THE UTERUS.

A Paper read before the Medical Society of King's College, London, Nov. 18, 1847.*

By Frederick John Hensley, M.B., Lond., Vice-President of the Society.

The causes which lead to this displacement of the womb may be divided into predisposing and exciting.

The predisposing are,—that congenital formation of the uterus, mentioned by Tiedemann, in which the uterus is situated obliquely, and the ligaments are lengthened; slight inclination and great capacity of the pelvis; relaxation of the tissues in the pelvis in general, and particularly of the broad and round ligaments; frequent abortions, by which the body of the uterus is rendered larger and heavier, and its neck relaxed and elongated, from repeated floodings; any cause which produces fulness and enlargement of the fundus, as fibrous tumours in that portion of the organ.

The exciting causes are,—accumulation in the bowels, whereby the pressure of the loaded ileum gradually forces down the fundus; falls; violent efforts to lift heavy weights, or any other inordinate exertion by which the abdominal muscles are brought strongly into action; straining at stool, and these causes of course act with greater force when they concur with any of the predisposing causes. Dr. Denman considered retention of urine to be the cause in the single case related to him by Dr. Thomas Cooper; it is, probably, more an effect than a cause. Tumours in neighbouring organs, as the ovaries, may produce the same effect.

Let us now proceed to consider the effects produced by this displacement, and which add greatly to the importance of an early diagnosis. They are numerous and serious. Time will not allow me to enter minutely into their symptoms, which indeed would form an ample subject for another communication, I shall, therefore, content myself with a brief enumeration of them.

In all cases where the fundus has remained displaced for some little time, congestion and engorgement, not only of itself, but of the cervix and os uteri, is produced, owing to the return of venous blood being retarded; this congestion is occasionally so great as to lead even experienced men into the belief that malignant disease of the os and cervix is present, or that the retroflected fundus is a fibrous tumour.

The cause being overlooked, and the congestion continuing, ulcerative inflammation of the cervix is apt to be set up, and a long train of severe symptoms ensues, such as pain and heat in micturition, bearing down, leucorrhœa, the discharge being yellow and thick, occasionally tinged with blood, and other symptoms too numerous to enter into. The relations of an organ whose sympathies extend through the whole female frame, insomuch that some writers have considered it the centre of female nervous sympathies, cannot be disturbed without generally producing many sympathetic affections, among which we may class nausea, vomiting, spasms, and the protean forms of hysteria.

Another affection very commonly associated with retroflexion, and to which I have alluded in describing the symptoms, is oophoritis, the peculiar symptoms of which are pain, heat, and tenderness in the corresponding groin, a sense of weight and swelling there, (the latter may be sometimes distinguished through the abdominal walls,) and what may, united with these symptoms, be almost regarded as pathognomionic of this affection, lameness of one leg, the patient being unable to extend the thigh without pain; she keeps it flexed on the abdomen. On examination per vaginam the swelled ovary may be felt, it is, however, more easily detected per rectum as an oval swelling posterior to and above the uterus, very tender to the touch.

Other effects are sterility, tendency to abortion, and dysmenorrhœa.

Retroflexion of the fundus tends, I believe, to produce

* Continued from page 14.

abnormal growth in the substance of the uterus, especially fibrous tumours, by occasioning congestion, and keeping up irritation and an increased flow of blood to the part. This is a point requiring further investigation.

Having thus described generally the symptoms, history, causes, and effects, of this very important displacement, I will proceed to illustrate the disease by the detail of one or two cases, premising that it is not to be expected that all the symptoms I have enumerated should be present in any individual case, and that the treatment adopted will be described more fully afterwards. For the first case I am indebted to Dr. Rigby's reports.

L. B——, aged 27, married three years, does not suppose herself ever to have been pregnant, tall, and well formed.

August 4th, 1845. Catamenia have always been regular, lasting six or seven days, but since her marriage they have been rather more profuse, lasting eight, or even ten, days; slight leucorrhœa during the intervals; digestion usually good; bowels confined; accustomed to active exercise; pulse very feeble; has a remarkably dry skin, which has been peculiar to her since her childhood; the feet have an irritable eruption on them, which at times itches severely. When she perspires, which rarely happens, it seems to relieve this source of irritation considerably; urine always high coloured, and turbid on cooling, occasionally with red sand, but never scanty.

Examination per vaginam:—Os uteri looking almost directly forward; the fundus uteri can be felt behind the vagina; uterine sound passed as far as the os uteri internum, the point being directed backwards, and by raising the fundus a little with the examining finger, the sound passed into the uterine cavity to its full extent. I then raised the fundus upwards and forwards into its natural position. She states that a very slight appearance of the catamenia occurred shortly after marriage; that in about a fortnight afterwards she received a severe concussion of the brain, in consequence of being thrown from a carriage with great violence, when it was upset. She went ten days beyond the next period; a slight show then came on, and again disappeared, but in twenty-four hours it returned very profusely, with an unusual degree of pain, and with the expulsion of several large clots.

R. Extr. Taraxaci, cochl. min. ½, omni nocte e lacte. R. Pulv. Guaiaci, Magn. Carb., utrq, gr. x., ex Aqua, cum Sp. Ammon. Aromat., dr. ss., omni meridie.

She left town immediately afterwards.

October 3rd. She returned to London on Sept. 30th, in good health; the course of medicine which she has been taking seems to have agreed well, and to have diminished the lithic diathesis, which formerly existed. I introduced an ivory supporter, fixed to a pessary as before described; it appeared to answer the purpose completely without producing any inconvenience; I therefore omitted to use an astringent lotion, as I expected that the contraction of the vagina would be sufficient to retain it in position. On her rising, however, into the upright posture, it slipped and came down the same evening.

4th. Introduced an ivory pin of the same flattened form as yesterday, and fixed it to Dr. Simpson's instrument for supporting the uterus; it was adapted with much ease, the os uteri having been gently dilated previously to the uterus being raised into its natural position.

7th. Rectified the instrument by slightly bending it, as it pressed more on one labium than the other.

10th. Catamenia appeared without pain; health good.

16th. Leaves town to-morrow to visit her parents at a considerable distance.

December 10th. I visited her for the purpose of removing the supporter, but on my arrival I found that two days previously, when rising from her chair, she accidentally trod on one of the tapes and pulled it entirely out.

Examination per vaginam.—The os uteri opened backwards and rather low down, the uterine sound passed easily in the right direction.

Dr. Rigby remarks, "The above case presents several features of interest. In the first place a considerable degree of retroflexion is ascertained to exist without its producing any derangement or inconvenience whatever; the only change which could have been attributed to it was the circumstance of the catamenia having been rather more profuse since than before her marriage. No trace of dysmenorrhœa or ovarian irritation had existed, not even the slightest degree of pain or uneasiness about the pelvis, nor was she at all aware of any difference in her feelings, either after I had replaced it, or when it returned to its former retroflected condition."

The history of the patient from the time of her marriage, to the unusually profuse catamenial period, which followed her accident, is interesting:—"A very slight appearance of the catamenia occurred shortly after marriage," a circumstance, where this function had been so regular, which would favour the supposition that conception had taken place, the more so as she was in perfect health at the time; then came the accident, which was accompanied by so severe a concussion, as to render her more or less insensible even for some days. She went ten days beyond the ordinary period, which is exactly the reverse of her usual habit, being inclined to have a return of the catamenia some few days short of the full time. The manner in which the discharge appeared was equally unusual:—"a slight show came on, again disappeared; but in twenty-four hours it returned very profusely, with an unusual degree of pain, and with the expulsion of several largs clots." The whole features of this period seem to me to indicate the occurrence of an extremely early abortion.

The necessary inference appears to be that conception had taken place very shortly after marriage; that she

was exposed to a serious concussion of the body as well as of the head, when advanced nearly three weeks in pregnancy, and when the uterus therefore was beginning to undergo that increase of vascular congestion, which is known to be one of the earliest changes it presents after conception, and by which its fundus being rendered more heavy and bulky than ordinary, would be peculiarly liable to be forced downwards and backwards by the occurrence of so serious an accident as that which she met with.

The next case I shall allude to is one which came under my own notice, and in which the symptoms were more serious. It is as follows:—

December, 1843. Marianne Nichol,* widow, aged 35, has been married sixteen years; had six children, (the last three years ago,) and one miscarriage. Catamenia appeared at the age of eleven years, and the discharge was profuse for a time, but shortly stopped for six months, and again returned, and from this time she had a continued discharge for three years. The monthly discharge is always regular during pregnancy. Ten years ago had a very difficult labour, and from that time has always been ailing. About four years ago she overstrained herself by lifting a heavy box, and since then she has suffered from pain in the back, and other symptoms referrible to the pelvic organs. For the last four months has had a pale offensive discharge, and pain and heat in micturition. At present complains of pain in the loins and left groin; also of pain down the left leg, with numbness; the urine is scanty, and causes pain in passing it; there is no frequent desire to pass it; bowels costive; has been in the habit of taking aperient medicines; defæcation gives great pain. The catamenia are preceded by much pain of a bearing-down character, shooting down the thighs, especially the left; the discharge is copious, dark-coloured, and attended with fibrous exudations and pain in the back; slimy leucorrhœa occurs in the intervals.

Examination per vaginam:—The os uteri is tender to the touch, and bleeds readily on pressure.

Examination per speculum:—The anterior lip is divided into several lobules, it is large and swollen; the posterior lip is covered with highly vascular granulations, and is fissured; the os uteri looks downwards, not backwards; behind the posterior lip is a tumour, hard and painful.

The nitrate of silver was applied to the uterus; Lotio Plumbi ordered for injection; quinine and sulphuric acid taken internally.

5th. Catamenia have returned this morning; feels very low and weak; suffers a good deal from dyspnœa.

On the 9th was ordered calomel and colocynth pill, and Acidum Hydrocyanicum, with Inf. Quassiæ, for the dyspeptic symptoms.

It would be tedious and irrelevant to the subject to enter into the symptoms dependent on dyspepsia, and an affection of the chest; I shall therefore confine myself to the uterine symptoms.

18th. The leucorrhœa has continued copious and offensive. To-day I scarified the os uteri, but it afforded little relief, as it did not bleed freely. The next day I applied eight leeches, which bled freely.

29th. Feels better; the catamenia have appeared, and are attended with less pain and bearing-down. On first trial I was unable to pass the sound, but on the 9th of January, having curved it more, I succeeded in doing so; it was felt in the tumour behind the vagina, and by turning it upwards and forwards, I removed the tumour, and restored the fundus to its position. The body was bent backwards, and to the right side; its continuity with the os was traceable by the finger.

She was discharged on the 30th, as I had obtained an order for her admission into the hospital for women, into which hospital she was admitted on the 10th of February, under Dr. Protheroe Smith. The retroflexion was found to have returned again, and the tumour was tender and painful.

Hirudines vj. cervici uteri applicandæ.

February 25th. The uterus was restored to its natural position by the aid of the uterine sound.

Hirudines vj. ori uteri.

28th. After the uterus had been restored on the 25th, there was great pain in the back and loins; leeches bled freely; bowels open thoroughly on the 25th.

Examination per vaginam:—The anterior lip is hard and nodulated; the os looks backwards into the hollow of the sacrum; the uterine sound passes easily to its full extent, with its concavity forwards, while there is now no tumour behind the neck of the womb.

March 3rd. The uterus is again distinctly retroflexed, as evidenced by the introduction of the uterine sound; bowels open. Hirudines vj.

20th. Uterus in its natural position; uterine sound passes with its concavity forward, and no tumour can be felt posteriorly.

27th. Uterus in its natural position. The patient is very hysterical.

31st. Uterine sound passes to three inches and a half in its natural direction, with its concavity forwards; the cervix is large and bulky; os irregular and indurated; no tumour posteriorly; the posterior pouch of the vagina indurated.

Pil. Ferri Sulph., gr. v., ter die sumend.

April 14th. Feels much better, but still complains of pain at the chest; a sensation as of hot water in the stomach; has a very offensive discharge; the pain in left groin has entirely disappeared, leaving a slight tenderness.

Examination per vaginam:—Uterus in proper position; the os less indurated; uterine sound passes with concavity forwards, and half an inch beyond the natural extent; the os looks distinctly backwards, and there is no pelvic tumour posteriorly.

She was subsequently made an out-patient. Occasional scarifications and mercurial pastiles were ordered, which after a time affected the system; a progressive improvement in the condition of the cervix

* Admitted into King's College Hospital, under Dr. Todd, December, 1845

and os took place, though the retroflexion returned once and again, but she was ultimately discharged cured.

This case furnishes an instance of the great tendency which exists in cases of long standing to a return of the retroflexion; it was remarkable for its obstinacy. The long duration of the treatment necessary to produce a cure should not excite our wonder, when we consider that the disease had evidently existed for some years, and had been overlooked, and consequently neglected; that it had led on to excessive engorgement of the cervix and fundus, and ulceration of the posterior lip; that the body and cervix were elongated, so that the sound at one time passed three inches and a half, and therefore Simpson's supporter was inapplicable. It was only after the ulceration had been healed by cauterizations, and the voluminous organ reduced by repeated leechings, and local mercurialization, that the disease was cured.

I might bring before you numerous other cases which have come under my own notice, but having detailed these, I deem them sufficient for my present purpose, and will not detain you long by dwelling on the general treatment.

In the first place the causes should be removed; the bowels must be unloaded, and kept gently open by saline aperients; the general health improved by alteratives and tonics; local engorgement relieved by leeches applied to the anus, or to the os and cervix uteri, followed by the warm hip-bath. The fundus must then be replaced by the uterine sound, and the patient enjoined to remain in bed on the side for some days. If the fundus remains in its proper position, so much the better; astringent injections will be all that is required. If otherwise, the uterus must be again restored, and perhaps by keeping the sound a short time in it, we may overcome the tendency.

Should this means fail, we must employ the uterine supporter devised by Professor Simpson, an instrument which I now exhibit to you. It consists of a metallic or ivory pin, the length of the uterine cavity, (two inches and a half,) fixed in a disc or button, on which the os uteri rests, connected with and kept in position by a little frame, resting on the mons veneris, and which is properly fastened by tapes. Dr. Rigby improved this instrument by making the pin flat instead of round, and broader at the extremity, so as to adapt it to a larger surface, and by employing ivory instead of metal. Dr. Simpson had removed the objection of corrosion being produced by the secretions, by having the metal electro-gilded. The instrument should be adapted while the patient is in bed, and she should be kept quiet for some days, till the uterus becomes accustomed to its presence. I have known peritonitis induced by the neglect of this precaution, the patient having walked home some distance; where, however, the patient is cautious in her movements, and disposed to follow the directions of her medical attendant, the instrument may be worn for months without inconvenience, and excites less irritation or discharge than the ordinary pessaries. The instrument is generally required to be worn a month or six weeks to effect a cure; after wearing it a short time the patient is able to take moderate exercise.

Dr. Simpson has another instrument for the same purpose, it is a species of pessary, to which he has fixed a hinge, by means of a spring, like the blade of a knife, but this I have neither used nor seen.

Into the treatment of the complications, it is impossible to enter minutely, I fear I have already trespassed too long on your time and patience.

SYMPTOMS OF POISONING, AFTER EATING A QUANTITY OF MACE.

By George C. Watson, M.D., Liverpool, formerly Lecturer on Forensic Medicine, in Dublin.

(Read before the Liverpool Medical Society. 1847.)

The subjoined toxicological effects of an article extensively used as a condiment, will, perhaps, justify their being placed on record under the head of narcotico-acrid, or narcotico-irritant; and it is the more necessary to establish the concentrated physiological action of the nutmeg and its singular envelope, because its culinary merits under a diluted form render its milder effects a subject of common experience, while its more intense action appears to be little known, at least as far as my research has carried me.

The entire indigestibility of the compact fibre of the arillus of the nutmeg is, perhaps, only matched by the nut it encloses, and suggests at once as the first step of treatment, an emetic, in order to remove from the stomach a substance which, many hours even after having been taken, shews great resistance to the combined processes of mastication and digestion, and requires a lengthened period for the full development of its toxicological effects. Most probably to this cause is to be referred the slow accession of the symptoms in the first place, and their obstinately prolonged duration.

Perhaps it might be doubted whether the treatment subsequent to the emetic was the most suitable, especially the selection of a remedy like camphor, which belongs to the same class of poisons as the one to which I have ventured to refer the present drug; but the smallness of the doses of camphor given puts it almost "out of court." The other diffusible stimuli seemed indicated by the symptoms, &c.

"At about eleven o'clock in the forenoon of the 12th, of March, 1847, I was in a sale-room in which there were samples of spices, &c.; and from curiosity, I ate about as much mace as could be lifted on a teaspoon, if broken small. About half-past twelve o'clock I felt

a pain on the crown of the head, extending over a space about the size of a penny piece; I also felt a slight nausea of the stomach, as if I had been smoking inordinately. I had kept eating the mace in small bits over about an hour and a half. I walked home, and dined about three o'clock. I still felt the pain slightly on the top of the head, and also the nausea and slight giddiness. I rose from dinner and looked out at the window, to dissipate, if possible, this disagreeable feeling. I then felt the blood rush to my head, but the feeling was as if an electric current had passed from the crown of the head downwards. Not wishing to be overcome in the room in which I then was, I made an effort, and got mechanically down-stairs. I then felt the same sensation which I should suppose a person would experience who had become nearly insensible from extreme cold, and that if I had yielded myself to its influence, I could have slept away out of existence without pain. I felt this sensation twice; the second time when I had got down stairs into the back parlour. I then walked about in the back yard, to endeavour to drive away the extraordinary sensations, but in a few minutes a cold shiver came upon me. I then got into the house, and laid myself npon a sofa near the fire. From that time I felt every variety of heat and cold from their respective extremes. At every time the blood went from and returned to my head, the current changed the sensation, sometimes feeling myself very hot, and the next very cold, but never the same sensation. I felt at one time such a pressure in the head, that it appeared as if all the blood in the body had rushed to obtain possession of that region, and I thought I could hear it gushing in my ears. These symptoms became gradually weaker. A medical gentleman was hurriedly called in, and some brandy was administered. The effect of this upon me was as if I had been electrified from the roof of the mouth downwards in a straight line, and dying off towards the feet; it then seemed to diffuse itself over the whole body. The state of my body generally felt as if I had had hold of slightly galvanized wires, the wires apparently working in antagonist directions, out of tune and keeping;—like, in fact, so many connecting rods working from excentrics out of truth, and jarring against each other. The state of the mind was, I sbould suppose, similar to that of the opium eater, entertaining no apprehension of the result, although aware of the presence of some danger. The pulse, during the several paroxysms, was very varied, being from 70 to more than 100. During the attack I felt every nerve in my teeth, but no pain."

The above description is, in the words of the party himself, whereby he has endeavoured to describe the anomalous feelings and intellectual disturbance produced so unexpectedly by the arillus of the nutmeg. Præcordial anxiety was remarkable, and the whole state of the patient induced the surgeon called in, first to administer hot brandy and water, and finding this of no service, he exhibited an emetic of sulphate of zinc and ipecacuanha, which brought away some trifling portions of the masticated mace. We now saw the patient together. The feet were cold, and required artificial heat; the head throbbed, eyes looked injected, and the countenance acquired a bizarre expression, whilst the words he employed to express his sensations seemed selected for their merit of being the opposite to what should have been used. Camphor mixture and compound spirits of ammonia, with chloric æther, were given at short intervals; the bowels were moved frequently by salts and senna, and the forehead was kept cool by a spirit lotion and strip of linen. His temporal arteries beat strongly for several hours. The persistence of the intellectual disturbance was remarkable, for on the third day the odd and excited state of the sensorium had not quite disappeared, so that he even then felt himself unable to attend to his office books. His thoughts hardly submitted themselves to his control, unless by a consciously great effort.

The arillus of the nutmeg contains an expressible oil, one eighteenth part of which is volatile according to Duncan. Upon the latter the flavour is said to depend, and probably also the excitant power upon the sensorium, although this has not yet been determined, that I am aware of. The properties of both mace and nutmeg appear to be identical, and reside in the essential oil found in them, for the aromatic flavour and pungency of which only have they been introduced into pharmaceutical and culinary economy. The stimulating properties are less grateful in the envelope than in the nut itself, yet the potency of the one and the other, when too freely used, in developing symptoms of an injurious kind in the human subject, renders it needful that a salutary caution should be urged against the too liberal use of these common condiments.

CASES FROM PRIVATE PRACTICE.*

By John Richard Wardell, M.D., Edin.;

Late President of the Royal Physical and Hunterian Medical Societies, Assistant Pathologist in the Royal Infirmary, Edinburgh, &c. &c.

Case V.

INFANTICIDE.

Post-mortem examination made on the body of a female child, February 1st, 1847, which had been found forty-eight hours previously, in an adjacent river.

External aspect. The body is in various places besmeared with mud, especially about the head and nates; cutaneous surface on face, neck, thorax, and anterior aspect of superior extremities of a pale livid hue; conformation of chest full and rounded. Umbilical cord torn, its extremity being ragged and unequally divided, is of a pearly white colour, and bright and shining, not at all contracted or shrivelled, and feels soft and flexible to the touch; indeed, seems

* Continued from page 688 of last volume.

little, if at all, different to the state in which it is found at birth. At three or four places along the course of its vessels, are observable congested-looking spots, of a reddish brown colour; no indication of any ligature having been employed; measures eight inches in length; no discolouration nor evidence of powerful traction having taken place at its abdominal insertion. Nates are smeared with an olive-greenish meconium. Hair light brown, and in the usual abundance. Finger nails fully developed, and reach a little beyond the tips of the fingers; nails on toes also perfectly formed. The white saponaceous matter, so usually seen at the birth of mature children, is present on several parts of the body, but mostly on back and nates.

The body, on being washed in tepid water, becomes of a more distinctly pinkish colour. On the anterior part of the neck a slight line is observable where the cuticle is excoriated; this line is four and a half inches in length, and in some portions of its course ecchymoses are apparent. On the left side, a little above the clavicle, is a discoloured patch, resembling a bruise; the superjacent cuticle is somewhat abraded; colour of a greenish blue cast, of the size of a sixpence. No other external traces of violence. Weighs 5lbs. 14½ oz. avoirdupois. Measures from vertex to heel 19¾ inches.

On making a vertical section, and reflecting back the scalp, a good deal of dark fluid blood has escaped from the posterior part. Cranial bones are not fractured. On removing the calvarium more dark blood oozes away, and the encephalic mass is much congested, the superficial and membranous vessels, as well as those proper to the substance of the organ, being of a very turgid appearance. Convolutions normally developed.

Dissecting back the skin corresponding with the line previously spoken of, on the anterior part of the neck, extravasation of blood into the subcutaneous cellular tissue is distinctly discernible, and beneath the bruised patch above the clavicle an irregular space from seven to eight lines in diameter, presents obvious sanguineous extravasation, and at three or four places in this space a small coagulum of blood, from the size of a wheat corn to that of a small pea, is discovered. The anterior surface of the sterno-cleido-mastoideus muscle shews one or two ecchymosed places, which, on a section being made through them, are found to extend into the substance of the muscle. No foreign body, nor anything anormal, is discovered in the mouth, larynx, pharynx, or trachea. Behind the pharynx, between the soft parts and the cervical portion of the vertebral column, some dark coagulated blood is observed.

Opening the thorax, the lungs completely fill the chest, and their anterior margins overlap the greater portion of the pericardium, so that only a triangular portion at the apex is left uncovered. The organs are of a pinkish red colour, but on their posterior inferior parts they acquire a blueish hue; diaphragm less convex than where the lungs are uninflated. Distinct crepitation is felt in every portion of their substance, and when thrown along with the heart and thymus gland attached, into water, the whole mass lightly swims on the surface. Each lung being placed separately in water, is extremely buoyant, and on each being cut into a dozen pieces, they all readily float; a piece taken from the posterior inferior part of the left lung (where there is congestion,) being powerfully squeezed by means of twisting it in the fold of a napkin, and then put into the water, swims as before. The lungs and heart together weigh 1175 grains; lungs alone 813 grains, and heart alone 362 grains. The heart contained some dark blood in the right side; foramen ovale still patulous; ductus arteriosus permeable, slightly contracted in central portion, and in it a small quantity of yellowish fibrinous matter is discovered; ductus venosus empty, but unaltered. On exposing the abdominal viscera the stomach is distended, and feels elastic to the touch; after placing ligatures around its extremities, it is removed, and on a puncture being made into its parietes, some gas has escaped, and the organ becomes collapsed; on laying it open, about a drachm and a half of viscid, mucilaginous, brownish-yellow matter is found; no morbid appearances detectible. Liver natural; intestines not at all distended, either with air or water, but rather seem contracted; the normal quantity of meconium is present. Other organs natural.

The following case occurred some few weeks subsequent to the above, at Malton, Yorkshire, and through the kindness of Dr. J. J. Wright, an intelligent physician of that place, who was employed by the coroner to make the examination of the body, I am thus enabled to present to the reader the subjoined example:—

Case VI.

INFANTICIDE.

Examination of the body of a male infant taken from a well, April 11th, 1847.

External appearances.—The body was carefully and tightly sewed up in flannel, beneath which was a second covering of cotton. The features and limbs were distorted and compressed by the tightness with which the coverings had been applied; the legs were firmly pressed upon the abdomen. A considerable quantity of meconium had made its escape, and was smeared over the lower extremities of the child and over the cotton cloth in which it was contained. Cutaneous surface of the head, neck, and shoulders, of a roseate hue, except on a part of the right side of the face and head where it was slightly livid; over the rest of the body it was pale. Some frothy mucus exuded from the nostrils The umbilical cord was torn off within a quarter of an inch of the abdomen; its extremity was ragged, colour a pale-red; there was no appearance of any ligature having been applied; there were no external indications of putrefaction. Hair light brown and rather more than usually abundant; nails fully formed, and reach beyond the ends of the fingers; the scrotum was slightly livid, it contained both the testes. No remains of membrana pupillaris. There were none of the sebaceous matter on any part of the surface of the body. Length from vertex to heel twenty inches; weight of body, 6lbs. ⅝oz., avoirdupois. There were no external marks of violence.

On making a section of the scalp from before backwards, a little effused blood was found over the superior

angle of the occipital bone. The cranial bones were unfractured, full, ossified, and not overlapping each other. The anterior fontanelle was unusually small; the posterior nearly obliterated. The convolutions of the brain were fully developed; the vessels of the membranes and substance of the brain unnaturally turgid and filled with dark-coloured fluid blood. Not the slightest putrescent odour was perceived on opening the chest. The lungs occupied the greater part of the chest, and partially overlapped the pericardium; they were of a deep pink colour posteriorly, their anterior margin being of a much lighter hue; they were perfectly healthy and crepitant. The heart, lungs, and thymus body being thrown together into water, floated considerably above its surface. Each lung was separately buoyant. When divided into thirty-six pieces, each piece floated, and after some of these had been very powerfully compressed in a cloth, their buoyancy was still preserved. Weight of lungs, 812 grains. About a drachm of reddish serum was contained in the pericardium; the heart was perfectly healthy and weighed 330 grains; the foramen ovale was open; the ductus arteriosus was contracted towards its aortal extremity. Trachea and the whole of the bronchial tubes full of frothy mucus; blood-vessels of chest unnsually full of dark fluid blood; stomach healthy, containing a little healthy mucus with some flatus; intestines filled with meconium. Other organs healthy.

(To be continued.)

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, JANUARY 26, 1848.

A numerous and influential meeting of medical practitioners, residing in the county of Dorset, has lately been held at Dorchester, at which the rules and regulations of the Dorset County Friendly Society, so far as they affect the medical profession, were taken into consideration. We have received a copy of such of the rules of this Institution as relate to the provisions for medical relief, from which we learn that the sum of two shillings and sixpence per head, from each benefit member, is paid to the medical officers;—that certain extra allowances, similar to those authorized by the Poor-Law Commissioners, are to be paid in protracted surgical cases and for capital operations;—that additional annual payments, "*which payments shall be understood to include all casualties whatever,*" are made for the families of benefit members, to the amount of two shillings for a wife or child above sixteen years of age, one shilling for each of the first three children under sixteen years of age, and nine pence for each additional child;—that ten shillings and sixpence extra is allowed for confinements;—that all medicines, &c., as well as attendance, are supplied by the medical officers.

We believe, that from statistical calculations, made with a view to this very object, the average annual period of sickness among healthy persons who come within the scope of these institutions, is estimated at six days and some hours. This average period will, however, vary with the circumstances of the individual families; their dwellings, habits, occupations, general state of comfort, and, above all, the density of the population, and sanitary state of the localities in which they may be congregated. For the large towns of the manufacturing districts, for instance, the calculation is far too favourable, and we much question whether, if we had sufficient data for determining this point with accuracy, the period of sickness given would not be found considerably below the truth, even among an agricultural population, and in localities favourably situated. Assuming, however, the above average to be correct, and estimating the families to consist of husband, wife, and three children, the sum paid by each will, in all ordinary cases, amount to seven shillings and sixpence; the number of days of sickness, without mentioning the hours, will amount to thirty, which allows the munificent sum of exactly three-pence per day as the amount of remuneration for medicines, attendance, the expenditure of time, &c., leaving out of the question the anxious devotion of mental labour and exercise of practical skill which the more serious cases necessarily call for.

Let us now recur to the proceedings of the meeting. We regret that we are unable to report them at length, but the resolutions which we subjoin, afford an epitome of them:—

It was proposed by Mr. Fox, of Weymouth, and seconded by Mr. Fooks, of Stalbridge, and carried unanimously,

"That although the Dorset County Friendly Society would be of great utility in administering to the wants of a large portion of the industrial inhabitants of the County; yet that in the absence of any restrictive clause as to the admission of Benefit Members, it is to be feared that many persons, whose circumstances do not require that Medical and Surgical Relief should be administered as a charity, would be induced to join the Society; it therefore appears desirable to restrict Medical Relief to the Labouring Population and Journeymen Mechanics."

Proposed by Mr. Cory, of Bridport, and seconded by Mr. Good, of Sturminster, and carried unanimously,

"That we regret exceedingly that the rules bearing upon Medical Attendance should have been framed without the Profession having been first consulted; and that consequently the offers of the Society are of such a character that, consistently with a regard to our own respectability, and a benevolent concern for the welfare of those who may become Members of such Society, we cannot accede to them."

Proposed by Mr. W. Highmore, of Sherborne, seconded by Mr. Emson, of Dorchester, and carried unanimously,

"That the Medical Profession has ever shown itself ready and willing to co-operate with gentlemen of liberal and benevolent minds in schemes having for their object the benefit of the industrious and provident poor; and in accordance with such feeling we invite a conference of the Committee of the Society with a Committee of Medical Men to be appointed by this Meeting, trusting by this means such regulations may be adopted as would be mutually satisfactory."

(Signed) G. CURME, Chairman.

The Members of the Provincial Association will, we feel assured, cordially respond to the sentiments so temperately embodied in these resolutions of their Dorsetshire brethren; but it will be difficult for many of them, notwithstanding the heartless treatment to which they are so often exposed in their intercourse with poor-law authorities, to believe that it could ever have been contemplated, even by the poor artizan or labourer, so to encroach on the gratuitous benevolence—for such in fact it is—of medical practitioners, under the fallacious plea of a payment for attendance, &c. Yet do we here see the lure held out, not to the necessitous merely, but to persons whose circumstances place them above such modes of obtaining relief in sickness. In this manner do we find the low rates of payment originally forced upon the profession by threats of competition, now extended from the actual pauper to the more independent, because more provident among the labouring poor, and with them to the small farmer and tradesman;—and who shall say where the evil is to stop?

It is true that a high reputation for talent will probably always obtain from the wealthy a corresponding honorarium, but the general body of practitioners, of every grade, if such practices are to go on, will systematically, though gradually, be depressed, until little prospect of attaining a competence by the exercise of their profession will remain, and no inducement, save the love of knowledge, for its own sake, or perhaps more rarely the pure desire of doing good, will be left for those whose minds are fitted for the duty, to devote themselves to so important and so honourable a calling.

Reviews.

A Manual of Elementary Chemistry, Theoretical and Practical. By GEORGE FOWNES, F.R.S., Professor of Practical Chemistry in University College, London. Second Edition. London. 1848. Fcp. 8vo. pp. 596. With numerous Illustrations.

The former edition of this excellent digest of chemical science has been received with general satisfaction, and we have only to recommend those who are not yet acquainted with the work, to avail themselves of the appearance of a second edition. Whether as a guide to the study of the various objects of which it treats, or as a work of reference for brief notices of the many newly-discovered compounds in organic chemistry, we can most confidently commend it. In the latter point of view, especially, it will be found most useful to those of our medical friends whose occupations may have prevented them from following out the progress of these discoveries.

Let us turn, for instance, to a series of these compounds, one of which has lately engaged so much of public attention. We allude to methyle, with its derivatives, chloroform, bromoform, &c. Wood spirit, of which methyle is the hypothetical base, not yet isolated, is a volatile inflammable spirit, obtained from the distillation of dry wood, much resembling alcohol, and analogous to it in its properties and modes of combination. The formula for methyle, is $C_2 H_3$. Wood spirit is the hydrated oxide of this body, $C_2 H_3$, $O + HO$ Wood ether is the oxide, $C_2 H_3$, O. Formic acid, a well-known animal acid, existing in the bodies of ants, and bearing the same relation to wood spirit, as acetic acid does to alcohol, is produced by the substitution of two equivalents of oxygen for two of hydrogen, $C_2 H O_3$; and chloroform is produced by the substitution of three equivalents of chlorine $C_2 H Cl_3$ for three of oxygen. We extract the following brief description of the analogous compounds with bromine and iodine, the former of which has been recently tried in Paris, as an anæsthetic agent, and found to possess similar properties with chloroform :—

"Bromoform, $C_2 H Br_3$, is a heavy volatile liquid, prepared by a similar process, [to that followed for procuring chloroform,] bromine being substituted for chlorine. It is converted by alkali into bromide of potassium, and formiate of potash. Iodoform, $C_2 H I_3$, is a solid, yellow, crystallizable substance, easily obtained by adding alcoholic solution of potash to tincture of iodine, avoiding excess, evaporating the whole to dryness, and treating the residue with water. Iodoform

is nearly insoluble in water, but dissolves in alcohol, and is decomposed by alakalis in the same manner as the preceding compounds."

Benzine, which we observe has recently been used as an anæsthetic agent at St. George's Hospital, by Dr. Snow and Mr. Cæsar Hawkins, is described as "a thin, limpid, colourless liquid, of strong, but not very disagreeable, odour, insoluble in water, but miscible with alcohol, having a density of 850, and boiling at 187° F.; the sp. gr. of its vapour is 2.738. Cooled to 32°, it solidifies to a white crystalline mass." Benzine is a compound of carbon and hydrogen, and is identical with the bicarburet of hydrogen, discovered many years ago by Mr. Faraday, in the liquid obtained from the compression of oil-gas. It is a product of the distillation from a mixture of crystallized benzoic acid and hydrate of lime. The anæsthetic effects, though decided, do not appear to equal those of chloroform or æther.

The London and Provincial Medical Directory. 1848. London. pp. 203 and 432.

We have great pleasure in recommending the "Medical Directory" for the current year to the notice of our readers. It is a great improvement on its predecessors, both in general arrangement, and in accuracy. Much useless matter has been discarded, and every effort seems to have been made to ensure correctness. The errors of omission appear to be chiefly, if not altogether, owing to the neglect of the gentlemen to whom circulars were sent, and the editor, as far as he has been able, has endeavoured to supply them by supplemental lists, in which the names are published, without qualifications. A useful form of medical diary is bound up with the work, and forms, together with a copious local list, arranged according to the several counties, and a list of the Poor-Law medical staff throughout the country, the leading features of novelty. We consider that the "London and Provincial Medical Directory," in its present form, is well deserving of the patronage of the entire profession; it will be found most useful in affording information on all such subjects as works of this description treat of, and as no expense seems to have been spared in the endeavour to render it an accurate record, we hope the proprietors will meet with a commensurate amount of encouragement.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Since the date of my last letter I have received the following contributions from correspondents. The first is from the learned translator and editor of "Paulus Ægineta," to whose commentary on the section on burns, (*Paulus Ægineta, vol.* ij., *page* 43, *Sydenham Society's Edition,*) I beg to direct the attention of your readers, as containing an able digest of the treatment adopted by the ancients:—

Answers to the Queries contained in Mr. Crompton's Letter to Drs. Heygate and Hastings, on the subject of Burns and Scalds,

By Dr. ADAMS, Banchory, Kincardineshire.

1. In the earlier part of my professional life I was accustomed to see burns generally treated on Kentish's plan, and I occasionally adopt it even now. When the patient at first could be got to endure the increased heat and pain produced by the turpentine for a short time, I have certainly thought that in the end it effectually removed the stinging pain of the burns, and when persevered in, that cases thus treated usually got round more speedily than under most other methods of cure. But I have often been obliged to put away the stimulant dressings, and have recourse to something more congenial to the feelings of the sufferer. I still frequently use a combination of turpentine with the resinous ointment as a stimulating dressing to the indolent ulcers resulting from burns. I never prescribe alcohol myself, but have known it answer fully as well as turpentine in some cases where it had been tried. The only pernicious consequences which I ever knew to result from the application of stimulants, have been a temporary aggravation of the patient's sufferings, and some increase of the fever. An inconvenience attending the use of turpentine in certain cases is the smell, which to some persons becomes in time very offensive. As a general rule, I would say that when the patient is of a nervous temperament, and of an impatient disposition, the stimulant plan should not be risked.

2. In cases of scalds of a limited extent, I would say that I have found nothing answer so well as cold applications. I usually lay a piece of surgeon's lint over the part, and keep it constantly wetted with cold water, until the heat and stinging pain be effectually removed. When this purpose has been accomplished, tepid water, applied in the same manner, will be found more agreeable to the feelings of the patient; but some prefer substituting cotton or flour. Many people in this district have a great partiality for warm poultices, and fancy that the patient experiences more relief from them than from any other means. The preparation from linseed-oil and lime-water is also extensively used, either alone or in combination with poultices. I cannot say that I think either of these very efficacious, but upon the whole they are safe applications. I would never think of using cold applications, as directed above, when the burning is of great extent, and I have heard of very bad consequences from the use of them in such cases by inexperienced persons.

3. Cotton I have long used, but my experience of flour is of recent date. When the burning is at the same time extensive and superficial, I look upon either the one or the other, as the most judicious application that can be used. But when the burning extends deeper, neither of them answers well, and some more appropriate application must be substituted in place of them, more especially the turpentine dressings.

4. After very extensive burns, I have commonly observed a great prostration of the vital powers, and have, therefore, generally administered wine and other stimulants to counteract this tendency. Brandy and

other spirits, however, I have rarely administered, and never ammonia, as far as I recollect. Of course all such means require to be given cautiously, or altogether abandoned, as soon as any febrile re-action takes place; but at a subsequent stage of the treatment they may frequently be resumed with advantage. Opiates I generally give where there is much suffering, but of course they require to be administered with proper caution when there is any morbid tendency to coma or sinking.

5. I have found burns about the head particularly fatal. Those about the feet are, of all others, the slowest in healing. Deep burns in the neck are obviously very dangerous, owing to the large vessels which are situated in that region. The only plan I have pursued in cases of apprehended danger from hæmorrhage, has been to avoid warm applications, and not to interfere much with the separation of the sloughs.

6. On this point I have nothing interesting to communicate. Of course the cicatrix will be the less marked the more the ulceration is prevented from spreading. I have never seen much done or attempted in such cases. I am not quite sure, however, whether I correctly apprehend the drift of this query.

7. I have rarely or never made an inspection of the body after death, as far as I can recollect; at all events I can find no report of any such case in my note-book.

8. My own experience in the treatment of burns has been principally confined to young and aged persons, and I have no hesitation in declaring explicitly, that when extensive, I have uniformly found them to be a most fatal class of injuries, and that when of a limited extent, they have frequently proved troublesome to heal, especially in old persons. In general I have found that death either resulted in the course of a few hours, the system having sunk under the shock it had sustained, or that the patient was gradually worn out by the pain and discharges. I have seldom known the febrile re-action to be so strong as to occasion death. In the case of a girl, about ten years of age, a fatal trismus was the consequence of a scald upon the neck and chest.

9. I cannot give any general rules for the management of such cases. In one case of burning at the ankle, where the tendons in front of the joint had become contracted, and the foot was getting into the state named *valgus*, I performed subsection of the *extensor* and *tibialis anticus*, with Stromeyer's knife, and then extended the foot, with the most satisfactory results.

10. Perhaps no better directions can be given to the public at large than to follow the practice of the common people in this district; which consists in first smearing the part with linseed oil, either alone, or mixed up with lime-water, and then wrapping it closely up with cotton, in a soft substance called wadding. To say the least of it, this application can seldom do harm, and it admits of being easily removed when required. A most serious consideration in such cases is the removal of the patient's clothes, which sometimes so adhere to the burned parts, that they cannot be removed without occasioning great pain, and tearing the flesh. I know not any directions which can be given for conducting the operation, except to perform it with great caution; and in doubtful circumstances, rather to wait the arrival of professional assistance, than run the risk of doing mischief.

11. I am not aware of any practical rules but what are sufficiently obvious, and founded on general principles. It must of course be admitted that the healing of a sore is the work of nature, and that all which the medical art can do is to remove anything which may obstruct this process. For some reason, which I have never seen satisfactorily explained, ulcers after burns have a strong disposition to become fungous. To these I usually apply the *unguentum æruginis*, or a piece of lint, wetted in a solution of sulphate of copper. In a few instances, when nothing that could be had would make a sore of limited extent put on a healthy action, I have applied a small blister for an hour or two, so as to produce sloughing of the fungus, and healthy edges of the sore. In such a case I have known mercury administered internally, with the intention of its acting as an alterative of the state of the system, but I would never think of following this practice now; the strength should rather be supported, and quinine given freely. In a case of deep burning about the elbow, where the humerus was laid bare to a considerable extent, I applied the actual cautery with good effect, in promoting the granulation of the bone.

12. Several instances of sudden death during apparent recovery have occurred in the course of my practice, but I have kept no report of any such cases. It does not occur to me that I ever met with a case in which death could have been referred to ulceration of the *duodenum*, although it would appear that such cases are not of unfrequent occurrence.

By Jesse Leach, Esq.,

Surgeon, Heywood, Lancashire, Fellow of the Royal Medico-Chirurgical Society, &c., &c.

Heywood, 10th January, 1848.

Dear Sir,

I am favoured with your letter of the 30th of December last, conveying your desire for my present opinion on the treatment of burns and scalds with treacle, and whether I have had occasion to change my views on this subject since my communication to the *London Medical Gazette*.*

* Mr. Leach's first paper "On the use of Treacle in Burns," is printed in the *London Medical Gazette*, vol. 23, page 192. The following extract may be useful to some of the members of the Provincial Association, by saving them the trouble of referring to the original essay:—"In the first and second stages of burns, I prefer the external use of treacle, which from its simplicity, readiness of access, comparatively little expense, and almost uniform success, cannot fail to recommend itself to every one. Before trying the use of treacle, I attempted cold water and spirituous dressings, protected with oiled silk, linseed oil, and lime water, but frequently failed in preventing the smarting burning pain arising from the sensitive state of the cutaneous nerves, till it occurred to me that treacle being a tenacious plastic, refrigerant liquid, when pure, would effectually exclude atmospherical air, while it would astringe and cool the inflamed part. The first case I used it in was attended with marked success; since then I have tried it in sixty-five cases, and with variable effects. Three things are necessary in its employment—first, that it should be free from sand, splinters of wood, and dirty water—with which some of it is commonly adulterated; secondly, that it should be spread upon fine bleached calico without any asperities from uneven threads; and, thirdly, that it should be cold. When used in this way I have frequently seen the most agonizing pain immediately cease, and turgescence

I have made some modifications in applying treacle since I published, having found layers of carded cotton upon the coatings of treacle supersede thin paper, which I at first used. Carded cotton is not liable to tear vesicles, which thin paper is, in any movement of the limbs. I have therefore abandoned the use of thin paper, where I can obtain carded cotton for this purpose, and use layers of carded cotton over a thick coating of treacle. In other respects I have the same opinion of the superior efficacy of treacle over any other application, in the treatment of superficial burns and scalds.

I invariably use terebinthinate applications in deep seated burns and scalds, and believe them preferable to those of treacle.

You will find the internal use of brandy and new milk, in the proportion of two tea-spoonfuls of brandy to a tea-cupful of new milk, agree with a patient's stomach when every other liquid is loathed, and the vital powers apparently giving way under excessive purulent discharges and constitutional irritation. The use of this mixture has a soothing effect on the nervous system, and speedily promotes healthy granulations in deep seated burns.

Faithfully yours,
JESSE LEACH.

Samuel Crompton, Esq.

By Wm. Eddowes, Esq., Surgeon, Pontesbury, and Coroner for Shropshire.

1. I always apply cold spirits of turpentine with a feather pretty freely to scalds and burns, as soon as I can after the accident—never repeat it; afterwards simple ointment, composed of oil, wax, and lard. I think the turpentine acts as a stimulant, and benumbs the sentient extremities of the nerves; I have never seen it do harm. I think the simpler the external treatment the better. Internal remedies are, in my opinion, of the most importance,—such as opium, calomel, tartar emetic, &c.

2. ———

3. Cotton may be very well, but flour is a nasty thing.

4. Calomel and opium firstly, afterwards combined with tartar emetic, and nitrate of potass.

5, 6, and 7. ———

8. Prognosis generally favourable.

9. ———

10. Burns would generally be avoided if woollen and linen garments were worn. Cotton aprons are the greatest source of mischief.

11. Tincture of iodine externally; opiates with tonics internally.

12. ———

I recollect seeing a child burnt to death, when the whole surface of the burn was so slight that a crown piece would have covered the worst part. It lived about twenty-four hours. Had no medical assistance.

[In reply to a letter in which I requested Mr. Eddowes to obtain *post-mortem* examinations after burns, he observes, "I will order *post-mortem* examinations in every case in future where I possibly can, and you shall have the results." I trust that the abstract of Mr. Erichsen's paper will satisfy medical men, that *post-mortem* examinations may throw considerable light on burns and scalds.—S. C.]

By W. H. Evans, Esq., Surgeon, Bath.

During my pupilage, in my hospital attendance, and while in an assistancy, I think I have seen burns and scalds, treated by every known plan. The result is, that in my own practice I invariably at first apply flour; cotton-wool is not so easily attainable, but I think quite equal in value as a remedy. I have seen the ointment recommended by Dr. Greenhow, and to which Mr. Markwick alludes in a recent letter to the Journal, assiduously tried, but do not remember a case in which the cure did not seem retarded. For simple and inextensive burns or scalds, gold-beater's skin or isinglass-plaster, I have found a very ready and effective dressing. I have never seen treacle used, but fancy it would be useful in such cases.

I will now answer your queries as they arise.

1. The stimulant plan of treatment I think objectionable, except in enfeebled habits, or where there has been great destruction of parts.

2. Cold is serviceable in burns of mild character.

3. Cotton or flour answer every purpose as primary dressings.

4. Sedatives, especially opiates.

5. Burns or scalds on the abdomen I consider dangerous in the highest degree.

6. Unremitting attention to position, and the suppression of extravagant granulations.

7. I have never examined *post-mortem*.

8. Prognosis should be guarded, for cases of mild character may be much endangered by nervous sympathies.

9. See 6.

10. Better to leave the public without *directions* as to treatment, when medical attendance is so readily gained. The best habits for children and persons incapable of avoiding danger, are made of wool. I have heard it said that any material may be made fireproof, by steeping in alum-water, but I should not

---

of the inflamed skin diminish. In mild cases, one dressing will suffice. Where vesication is large and extensive, I have frequently evacuated the contents by means of a fine-pointed needle, avoiding laceration of the detached skin; but oftener prefer a thick coating of treacle upon the part, and afterwards enveloped with cap paper, which, from the delicacy of its structure, will sooner tear than suffer the raised epidermis to be detached. In common cases, where the burn is slight, I spread the treacle upon fine calico, and apply it after M. Velpeau's plan, around the affected part. Where calico of the description mentioned, is not to be obtained, I use paper, with similar results. Where destruction of the skin has taken place, and the part has become a sore, I have thought treacle promoted suppuration

and retarded the cure; in these cases I have used the Ung. Plumbi Co., of the new Pharmacopœia, after M. Velpeau's plan, with great advantage." * * * "Where suppuration can be prevented it is very desirable that it should be, and I have seen some rare cases, where the injury appeared very great, get well in the course of a few days, under the treacle dressing, when aided by a good constitution." In a subsequent number of the *Medical Gazette*, vol. 23, p. 350. Mr. Leach says, that tissue paper is better than cap paper, and further, that when suppuration does not occur, he washes the treacle off at the end of five or six days, and generally finds the part well. He, however, says, that he has *tried it in deep burns, but cannot recommend its use in these cases.*

like to risk it; dresses of muslin and gauze, or such light textures, should be avoided for all such persons.

11. The most useful, and most generally applicable, is to aid nature in her efforts, and this, I take it, will always lead to the support of our patients' strength, and a mild *nursing* of his wounds. The water-dressing in most cases is to be preferred.

12. I do not know a case.

I remember a very severe *scald*, of the abdomen, by boiling broth, in a child four years old, where there was great threatening of the nervous system, checked however by the use of mild opiates. The case was dressed with lime-water and linseed oil.

The next communication is from Mr. Edwards, the partner of Mr. Coleman, of Wolverhamptom. Before I received this eminently practical paper, I had been informed that Mr. Coleman had been very instrumental in making known the value of cotton as a dressing for burns among the practitioners of Staffordshire, and it was my intention to have written to him on the subject; but the necessity for so doing was done away with by Mr. Edwards's clear statement of the method of treatment which he pursues.

By GEORGE EDWARDS, Esq., Surgeon to the General Dispensary, Wolverhampton.

Living in a district where burns and scalds are of daily occurrence, I hasten to comply with your request, and relate the result of my observations as to their best mode of treatment. I will endeavour to be as concise and practical as possible in what I have to say upon the subject.

First, then, with regard to internal remedies. In those cases where the shock to the nervous system has been so great as to endanger life, and render internal remedies the first and immediate consideration, I have invariably found stimulants of wine, brandy, æther, or ammonia and opium, most efficacious; but, as I have usually found the sensation of extreme cold to be the most urgent suffering evinced by the patients, in all extensive burns and scalds, and which I believe is mainly owing to the exposure of the denuded surface to the atmosphere, I at once proceed to the use of those means, the application of which will, most thoroughly and effectually, exclude the air from the injured parts. This materially aids the internal remedies in restoring re-action; indeed, I consider it of paramount importance.

External Applications.—If the injury is so situated that cotton can be properly applied, I always use it in preference to any other application. By cotton, I mean well-carded cotton, not that cotton-wadding which is sold in the shops, and is glazed on one side, to pad ladies' dresses with: this is a very poor substitute. If, however, the face is the seat of injury, the application of boiled linseed oil, or white lead, or thick white paint, answers the purpose better than anything I am acquainted with, for by drying upon the part, it forms an impervious covering, and effectually excludes the atmosphere. With these remedies I am prepared to say that all burns and scalds, (whether the destruction of parts is deep, and the surface considerable, or whether simple vesication only is the result,) will be more efficaciously combated than with any other. I know that by some practitioners these means are said to fail. I also know, that it is not the means, but the manner of applying them, which gives rise to failure. If cotton is used, it must be applied evenly, in large quantities, and retained in its position by the loose adaptation of a soft bandage. If boiled oil or paint be the remedy, its application should be repeated as often as it hardens upon the surface, until such a coating is acquired as to render it a perfect mask, and quite impervious to the air. When there is an accumulation of discharge under the mask, it must be evacuated by cutting a small portion of the coating away in several places, and afterwards fill up the openings by a fresh application of the paint.

Of course the repetition of the cotton will depend upon the extent of injury and amount of discharge. Frequently I find one or two dressings sufficient to effect a perfect cure in a burn which would require weeks or months to accomplish by the daily application of ointments; and to those who are familiar with the cries of distressing agony which always accompany the matutinal exposure of a burn, I need not point out how greatly superior must that plan be where the dressings have only to be changed once in every week or nine days.

The last communication which I forward for insertion in this number of the Journal, is

By GEORGE KING, Esq., Surgeon to the Dorcas Lying-in Charity, Bath.

Although my experience in the treatment of burns and scalds may not have been so extensive as that of some others, I expect in twenty-seven years of practice as a general practitioner, I must have had my share. In all the cases I have adopted the stimulating plan of treatment, using the Linimentum Terebinthinæ. I add a little more turpentine than is ordered in the London Pharmacopœia; with this addition it is more easily spread. Internally, Tinctura Opii and Mistura Camphoræ, which not only relieves the pain, but allays the nervous excitement; when the shock to the system is very great, brandy in gruel. I have seen very slight burns or scalds over the chest and abdomen of children prove fatal long before there had been time to see the effect of the local treatment; this leads me to think that we do not pay that attention to the constitutional treatment that we ought. When the arm, hand, leg, or foot are the parts burnt or scalded, I apply a bandage, first saturated with cold water, over the turpentine dressing, and request the patients to keep it wet with cold water so long as they find it agreeable and pleasant to find the gentle pressure of the bandage support and add to their comfort. I do not remove the first dressing for a day or two, or longer, if no complaint is made. As soon as suppuration takes place, which is often very profuse, I apply dry lint; this and the pressure of the bandage keep in check the sprouting granulations, and do much to prevent those disgusting cicatrices which we often see after burns and scalds. This mode of treatment will apply to your fifth and sixth questions.

I have also received communications from Dr. T. H. Barker, of Bedford; Mr. Newnham, of Farnham; Mr. Wood, of Rochdale; and Dr. Glass Black, of Torquay.

I am, Sir, Your obedient Servant,

SAMUEL CROMPTON.

THE "IMPERMEABLE PILINE" A REMEDY FOR BURNS.

By Alfred Markwick, Surgeon to the Western German Dispensary, &c.

Although various plans of treating burns and scalds have been recommended by different writers, still the *chief* indication seems ever to have been to exclude the air from the injured part, and thereby alleviate as speedily as possible the sufferings of the patient. The remedies, therefore, that have been employed in these cases, have all been more or less directed towards accomplishing this most desirable object. Indeed it is evident that this must always be of paramount importance, inasmuch as the prognosis is found to be dependent more on the *extent* than on the *severity* of the injury, for, as is well known, burns and scalds, even of the first degree, when *extensive*, often prove fatal, entirely in consequence of the pain they occasion. In his valuable "Dictionary" Mr. Cooper remarks, "I believe that one of the most important principles in the treatment of burns, is to exclude them as much as possible from the air, and that it is in this way that the treatment with powdered chalk, the linimentum calcis, the linimentum terebinthinæ, flour, &c., proves very commonly advantageous. In particular, several of these applications supersede all occasion for an early or a frequent removal of the dressing, and exposure of the part. When it is considered what agony is thus prevented, we cannot wonder that the simple application of flour should have come into extensive favour." And we find this opinion corroborated by the following paragraph, translated from the article on "Burns," by MM. Marjolin and Ollivier, in the "Dictionnaire de Médecine:"—"The first indication to be fulfilled is, as we have said, to subdue the violent pain which generally accompanies burns. Several topical applications we have seen, have been recommended, and are had recourse to, in order to obtain this result."

In my last communication I stated that I had found nothing to answer the purpose so *effectually* as the *impermeable piline*, and my object on the present occasion is to lay before my fellow-members of the Association the cases upon which that assertion was founded.

Case 1.—Was that of a servant of my own, who scalded the back of her thumb very severely with a piece of boiling-hot *soft* potato. Vesication of the whole surface was immediately produced, and, as might be expected, very considerable pain occasioned. A piece of "piline" was quickly applied, and sewed tightly round the part. The pain soon subsided, and in two days a perfect cure was effected.

Case 2.—A person burnt his hand with a red-hot iron; considerable pain and inflammation was the result; speedy relief, however, to both was afforded by the application of the piline, and the following morning the part was sufficiently restored to be left uncovered, and enable the patient to perform his accustomed duties.

Case 3.—A lady, residing at Halsey Terrace, Chelsea, in coming down stairs, put her foot into a jug of nearly boiling water, which the maid-servant had carelessly left there. The part at once became exceedingly painful and tender, and on removing the stocking was found to be much inflamed. A simple piece of rag was at first applied, but finding no relief from this, she was recommended by a friend to try the piline. She did so, and to use her own words, "found relief almost immediately after."

Case 4.—A gentleman living at Kennington, while sitting by the fire, taking his tea, upset from the mantle-piece a cup of very hot coffee, which fell on the inside of his left leg, just above the ankle. Violent pain was produced, and on removing his slipper and stocking, the part was seen to be considerably inflamed; the epithelium, however, was not raised. He immediately applied a piece of piline firmly round the part, and, to use his own expression, "was relieved from all pain in about ten minutes, and on the following morning not the slightest tenderness remained."

The great advantage of the piline in the treatment of burns and scalds appears to me, from the foregoing cases, to consist in *perfectly* excluding the air; in rapidly relieving the pain, tenderness, and inflammation; and though last, not least, in promoting the restoration of the secreting functions of the injured part,—a circumstance of no little importance, when we consider how much our well-being depends on the due and proper performance of the cutaneous transpiration. Indeed the *post-mortem* appearances met with in some parts of the intestinal canal have been attributed by Mr. Curling to the endeavour on the part of the duodenal glands, "by an increased action, to compensate for the suppression of the exhalation from the skin," giving rise to irritation and subsequent inflammation and ulceration.

While on the treatment of burns I may allude to the benefit that has been afforded by the "spongio-piline," in those cases where the epidermis has been destroyed.

Case 5.—A child about twelve years of age, in poking the fire, upset the kettle, the boiling contents of which fell upon both feet, scalding them very severely. The stockings were removed as quickly as possible, but the epidermis, which had been raised in several places, became lacerated in doing so, and was found adherent to the inside of them. The scalded surfaces then presented a raw and very inflamed appearance, and were excruciatingly painful. The child rolled himself on the sofa, and could not contain himself from the agony he was in. A piece of soft linen rag was applied to the injured parts, and over this a piece of "spongio-piline," wrung out of hot water, which was fastened on by means of a roller, and wetted once or twice in the twenty-four hours. In the course of ten or fifteen minutes the violence of the pain became subdued, and in an hour afterwards perfect ease was obtained. The "spongio-piline" was persevered in for about a week when the parts were completely restored.

Case 5.—The subject of this case was treated by Mr. Babbage,* with the material in question. I am

* I have written to this gentleman requesting that he would send the particulars of this case, and the result of his experience generally in the treatment of burns, for insertion in the *Provincial Medical Journal*.—A. M.

indebted for its history to a niece of the patient. It appears from this person's statement that her aunt, (an elderly and infirm person,) while sitting at work one evening, set fire to her cap, and before she could extinguish it, one side of her face was severely burnt, so much so that the cheek bone was exposed. Mr. Babbage was sent for, and ordered the "spongiopiline" to be wrung out of hot water and applied. This was done and persevered in with considerable benefit for a fortnight, granulation and cicatrization proceeding most favourably under its influence. A piece of lint, covered with some simple cerate was then placed between it and the wound, and continued for a few days, when the part was found to have completely healed. In this case scarcely any appreciable scar was left, notwithstanding the severity of the burn. May not the continued application of moisture, as in this instance, be the means, in conjunction, of course, with maintaining the parts in a proper position by bandages, of preventing many of the frightful deformities that so frequently result from severe burns?

19, Langham Place, January 3, 1847.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY,

October 7th, 1847,

JOSEPH WICKENDEN, Esq., in the Chair.

Dr. Mackay brought before the Society the following specimens of disease:—

SCIRRHUS UTERI,

Taken from the body of a woman aged 40, the mother of several children. She died of exhaustion from frequent uterine hæmorrhage, excessive pain in the region of the uterus and sacrum, which existed more or less severely for three years, and diarrhœa. The ulcerative process had destroyed the os, cervix, and the body of the uterus, excepting a portion of the fundus, about the size of a common nut, and had extended into the bladder and rectum.

ABSCESSES OF THE LIVER: JAUNDICE.

The liver was taken from the body of a woman aged 54, who six weeks before her death was seized with inflammation of that organ, followed by profound jaundice. The inflammatory symptoms speedily subsided, but the jaundice continued until death. The ductus communis choledochus was blocked up by a gall-stone; the gall-bladder was full, its mucous coat ulcerated in several places; and in the liver was found several abscesses, containing a dark green fluid of the consistence of thick cream. The proximate cause of the inflammation and jaundice appeared to be the impaction of the gall-stone in the duct, inducing destruction of the cyst, ulceration of its mucous coat, and subsequently inflammation of the substance of the liver.

FRACTURED RIB,

Taken from the body of a man who died of pneumonia. The body was examined under the coroner's precept in consequence of his widow's alleging that he had died from the effect of blows upon his chest, inflicted by a fellow-workman. The existence of fracture appeared to substantiate the charge, and to criminate the alleged assaulter, who had been taken into custody, but careful inspection shewed that the fracture must have occurred long antecedent to the date of the alleged injuries; the prisoner was consequently acquitted.

NUTMEG DISEASE OF THE LIVER,

Taken from the body of a married woman, aged 56, who had for many years been in the habit of drinking "moderately" of gin. For the last two years of her life she complained of anorexia and rejection of all food.

FATTY TUMOUR.

Mr. Elkington presented a quantity of fatty matter having the appearance and consistence of common beef dripping. It was removed from a recto-vaginal tumour during labour. The tumour considerably diminished the capacity of the pelvis, and prevented the descent of the child's head. It was punctured per rectum with a curved trocar, and the contents, when drawn off, were of the consistence of thick cream, becoming firm when cold. The patient was afterwards delivered by craniotomy, and recovered slowly, after two or three attacks of inflammation.

November 4th, 1847,

R. L. BAKER, Esq., in the Chair.

Mr. Simons brought before the Society a larynx taken from a patient aged 48, who had died from acute laryngitis, ten minutes after the operation of tracheotomy had been performed.

MULBERRY CALCULUS.

Mr. Dampier exhibited a large mulberry calculus, weighing four ounces and one drachm, taken from a patient by the operation of lithotomy.

Mark Heywood, aged 42, short, stout, and well proportioned, came under my care in May, 1847, suffering from symptoms of stone in the bladder; urine sometimes alkaline, at others acid, for which he was treated accordingly. On introducing a sound, a calculus of considerable size was detected, very rough. He went on for some time, during which the symptoms became more urgent and distressing. In the end of June I again sounded him, when the sound struck the calculus the instant it entered the bladder, which convinced me it was of considerable magnitude. I then proposed the operation of lithotomy, to which in a few days he agreed. I accordingly fixed the 6th of July, on which day, having previously prepared the patient by medical treatment, I performed the lateral operation of lithotomy, in the presence of Dr. Bell Fletcher, Messrs. Laurence, Cooper, Walker, and Langston Parker, who kindly held the staff for me, when I succeeded in extracting a mulberry calculus, coated by the phosphates, about the size of an orange, of a rocky form, like a piece of sea coral, and weighing four ounces and sixty grains. The patient progressed favovrably for four or five days, when orchitis attacked him, but he ultimately recovered, and is now gone to work in good health.

Mr. Carter exhibited a specimen of medullary cancer of the liver, taken from a female, aged 58. The liver weighed ninepounds thirteen ounces.

Mr. R. L. Baker exhibited the fibrinous contents (presenting a peculiar laminated form,) of an encysted tumour, taken from the abdominal parietes of a man, aged 48 years.

ANEURISM OF THE ARCH OF THE AORTA.

Dr. Fletcher exhibited a sacculated aneurism of the arch of the aorta.

Mr. S. first became a patient of Dr. Fletcher's in consultation with the late Mr. Benbow, on the 24th of January, 1846. He then suffered from an affection of the head, shewing itself in vertigo, loss of memory, and want of power to express himself; there was no paralysis. This state was ameliorated by rest, and increased by exercise or excitement. Leeches, rest, and attending to the secretions, and absence from all sources of excitement, in the course of three or four weeks brought the patient into a better state, and he lost all the symptoms of cerebral affection. At this time, on examination of the chest, an aneurism was discovered, the upper portion of which passed up into the neck, just behind the sternal attachment of the left sterno-cleido-mastoid muscle. It had not caused the patient any local inconvenience, neither did he know of its existence. A seton was placed in the back of the neck, directions given to him to abstain from anything like exertion, and to live a quiet and sedentary life, and be particularly careful to live upon a low diet, and avoid all stimulants. Dr. Fletcher did not see Mr. S. professionally, until September 27, 1847, but had occasionally seen him and knew that he was going on well, and that the aneurism did not increase in size. At this time Mr. S. was suffering from intense pains in the left shoulder and arm, of a rheumatic character; they subsided under the administration of purgatives, followed up by Dover's powder at night, and a mixture containing full doses of iodide of potassium, with small doses of the wine of colchicum, but were soon succeeded by a slight attack of peritonitis, which gave way to the usual remedies, and he was again convalescent. The aneurism was at this time in the same state as when first discovered.

On the 26th of October, Dr. Fletcher was again summoned to attend Mr. S., and found him suffering from another attack of peritonitis, attended with excessive depression; and although the extent of inflammation did not appear to be great, still it was evident that he was in a very dangerous state. The usual remedies were adopted, the pains of the abdomen subsided, and yet he sank and died on the 28th, only three days from the attack. He did not appear to sink from the effects of the inflammation so much as from the inability of his system to resist the depressing effects of disease.

Post-mortem examination 30 hours after death.—The head was not permitted to be examined. *Chest:* Heart healthy; aorta dilated and much studded with atheromatous deposit; an aneurism was situated in the arch of the aorta, between the origins of the arteria innominata and left carotid, and extended upwards about four inches, crossing obliquely the course of the trachea, so that its apex was situated under the origin of the left sternal attachment of the sterno-mastoid muscle. Into the base of the aneurism opened the arteria innominata, and the right common carotid, and the subclavian arteries on their respective sides, close at its base. The opening of the left subclavian was almost obliterated; it allowed the passage of only a very fine probe. The aneurism was divided into two sacs, by a band across its posterior wall, about two thirds of its height from the base; both sacs were filled with very firm clots, composed of transverse layers of fibrin, very firmly adherent to the walls of the aneurism, and to each other, so that the aneurism may be said to have been undergoing the process of a natural cure. Immediately after giving off the left subclavian, the artery was of its normal state and size. Lungs healthy; some old adhesions of the pleura on each side. *Abdomen:* There was slight effusion into the cavity of the peritoneum, and a thin layer of lymph thrown out upon the small intestines; liver, spleen, and pancreas healthy; kidneys, and viscera of the pelvis, healthy.

December 2nd, 1847,

WILLIAM DUFTON, Esq., in the Chair.

Mr. Green exhibited a specimen of syphilitic ulceration of the larynx, taken from a female who had died rather suddenly.

Mr. Carter brought before the Society a specimen of a diseased ovary, of a malignant character, with an entire cyst attached to it, containing about six gallons of fluid.

PENDULOUS TUMOUR OF THE BREAST.

Mr. Keeley exhibited a pendulous tumour, (with a drawing of the same previous to removal,) which he had removed from a female lunatic.

Hannah Reynolds, aged 45, single, of spare habit, and nervous temperament, was admitted a patient into Duddeston Hall Lunatic Asylum, in the year 1840. She came from Stafford County Asylum, and was a chronic maniac. When admitted she had a small tumour, about the size of a walnut, on the inner side of the right nipple, and close to it. It continued increasing in size, and gradually assumed a pendulous form, and in December, 1845, she was advised to have it removed, to which she objected. In six months afterwards I again examined it, and on account of its emitting a very offensive odour, which proceeded from moisture in its numerous clefts, I again recommended its removal, but she positively opposed it, her reason being, to use her own words, "that it was her weather-glass, she could tell when it would rain and when it would be fair, and she would not part with it for the world." It increased gradually till a month ago, (November, 1847,) when my attention was again called to it by the nurse. It was then larger than at present, having collapsed since its removal; its surface was very unequal, having numerous elevations and clefts, very similar to a cauliflower. It appeared to consist of three

lobes, the middle one had become gangrenous, and highly offensive, so much so that the patient herself desired to get rid of its; she had lost her appetite, and was languid; I therefore at once, while she was in the mind, passed a ligature round the pedicle, half an inch from its origin, and another an inch from that, and divided it between them with scissors. Not a drop of blood was lost, and the patient was very much delighted at having got rid of so troublesome a companion. The ligature came away in the following week, and the part is now quite well. It is remarkable, as being the only case published, except one in the "Dublin Quarterly Journal," for November last, where there is an excellent paper on the subject of pendulous tumours, by Dr. O'Ferrall, of Dublin.

SHEFFIELD MEDICAL SOCIETY.

Seventh Session.—Fourth Meeting, Nov. 18, 1847.
The PRESIDENT in the Chair.

INTUS-SUSCEPTIO.

Dr. Bartolomé exhibited a portion of ileum, presenting in about twenty inches of the intestine *four* intus-susceptions, taken from the body of a girl aged 5¾ years. She was taken ill on the 4th of November, about nine in the morning, suffering from pain in the back and constant vomiting, and when seen by the assistant of a medical practitioner late in the evening, she was moribund. An inspection was made on the 7th. The body was stout and well formed, and presented no abnormal appearances externally. The membranes of the brain were congested; the puncta more distinct than natural. The lungs were much congested on the posterior surface; the left lung hepatized at the root; the heart healthy; the left ventricle contained some fibrin. On raising the omentum, a portion of the ileum was found to be intus-suscepted, and further search exhibited three other intus-susceptions, occupying about twenty inches of the intestine, the two upper ones being within six inches of each other; the others further apart. The stomach was healthy, but pale, containing about two ounces of a yellow viscid fluid; spleen congested; intestines pale, healthy; kidneys normal, but much congested; liver much congested, particularly in the right lobe, the peritoneum covering it, and the diaphragm in contact with it, almost black with congested blood.

The President exhibited some perchloride of formyle which he had just received, and Mr. H. Jackson read an account of it, as given in a pamphlet which had been forwarded to him by Dr. Simpson, of Edinburgh.

STRICTURE OF THE ŒSOPHAGUS.

Mr. Barker then detailed two cases of stricture of the œsophagus, one terminating fatally, and the other in recovery. The subject of the first case was a married woman, aged 30, who had up to the commencement of the disease enjoyed perfectly good health. The account given was, that eighteen months ago, she experienced some difficulty in swallowing solid food, which continued without being considered of any moment for a period of six months. At that time it was mentioned to her medical attendant, who appeared to consider the case as one of globus hystericus, depending on her then state of pregnancy, and treated it accordingly. The difficulty still, however, continued, and in a short time she found that she could only swallow liquids. It was then deemed advisable to introduce the œsophagus bougie, which was done several times, causing a good deal of pain, and after this the sputa appeared tinged with blood. No relief followed and the deglutition still continued very difficult. About three months ago, a small abscess presented itself on the left side of the neck, about an inch and a half above the clavicle, which was evacuated by the lancet, and in a few days healed. In a short time a natural opening was formed posterior to the sterno-cleido-mastoideus muscle, just above the clavicle, through which pus was discharged, together with a great part of the liquid food she took. She continued for some weeks in this state, and at length sank from pure exhaustion.

On inspection *post-mortem*, a stricture of the œsophagus was found opposite to the fifth cervical vertebra, posterior to which an abscess was found communicating with the œsophagus both above and below the stricture; and there was also a fistulous communication from it to the external opening in the neck, so that any liquid swallowed passed first into the abscess, and part was conveyed through the opening below the stricture into the stomach, and part passed through the outer opening in the neck. It appeared, then, that the sac formed by the pressure of food in the œsophagus above the stricture had ulcerated, or that a false passage had been made by the bougie, and the food passing through the opening, made its way into the cellular tissue surrounding the œsophagus, and in consequence, an abscess was formed. It is most probable that when the abscess formed, some of the liquid food might pass the stricture, but that in a short time the constriction became still greater, and *all* the food passed first into the abscess itself. The anterior surface of the fifth and sixth cervical vertebræ was denuded of periostium; but there was no softening. This, Mr. Barker attributed to the pressure of the pus previously to its evacuation by the external opening. It appeared as if nature had set up two provisional actions,—one to relieve herself of a foreign body which was effected by the external opening, and the other a vigorous effort to furnish nourishment to the stomach, which was to a certain extent accomplished by the communication formed below the stricture, through which part of the food (but not sufficient to support life,) was conveyed.

The second case was that of a lady of delicate habit, far advanced in pregnancy, who had swallowed by mistake a small quantity of the strongest Liquor Potassæ. She had taken about a table spoonful into the mouth, but only a few drops, in all probability, passed into the œsophagus, as she of course immediately detected the error from the intense pain. She was seen by Mr. Barker in about twenty minutes, when he found her suffering from severe burning pain in the mouth, œsophagus, and stomach, with violent retching,—in fact, from all the symptoms of poisoning by caustic poison. The usual

remedies were immediately had recourse to, and in a few days she was comparatively comfortable, but still complained of pain in the œsophagus and stomach, and could only take small quantities of liquid food. About a fortnight after this accident she was confined, and recovered very well. The child died on the second day after its birth. For some weeks she suffered from painful and difficult deglutition, and at times, for two or three days together, she could not take any food, so that it was necessary to administer enemata of broth. Six months after a bougie was passed and a stricture was detected at the lower extremity of the œsophagus. This was repeated at intervals of two or three days for a period of two months, when she became much relieved, but has still occasionally difficulty in swallowing food, especially if not well masticated, and is compelled to have occasional recourse to the bougie. The successful termination of the case in the first instance Mr. Barker attributed to the fact of the poison having been taken directly after a full meal, as he believed that a very small quantity would, under other circumstances, have produced much more serious, if not fatal results, upon the stomach.

The discussion chiefly turned upon the first case, as to the origin of the communication from the abscess with the œsophagus, below the seat of stricture.

Foreign Department.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE, PARIS

LITHOTOMY AND LITHOTRITY.

In continuation of the discussion on the merits of lithotomy and lithotrity, M. Leroy read an address in which he examined, in succession, the following questions:—1. *Are explorations with the lithotrite useful in detecting the conditions of the bladder which are associated with urinary calculi; can they be made without danger, and ought they from their severity to be regarded in the light of operations?* 2. What inconveniences are attached to lithotrity? 3. What influence is exercised over the operation by the state of the bladder, the prostate, the urethra, and the kidneys? 4. What is the influence of age over lithotomy and lithotrity respectively? 5. *Are the attempts to lithotritize injurious to the subsequent performance of lithotomy? What is the influence of method upon the results of lithotrity?* In reference to the first question, the author determines, that as far as exploration is concerned, no advantage is possessed by the lithotrite, which is not equally attainable by the sound; and that exploration with the lithotrite is to be regarded as an operation, as respects its effects. In answer to the second question, M. Leroy decides that lithotrity is more likely to be followed by relapse than lithotomy; that vesical catarrh is more common after lithotrity; that it may give rise to retention of urine, by causing injury to the neck of the bladder. M. Leroy has cut fourteen octogenarians; of these he only lost one. In children he considers that the two operations afford even chances of success. The most expeditious method he thinks preferable;—lithotrity for small stones, lithotomy for large ones. On the question, whether attempts to perform lithotrity render the subsequent operation of lithotomy more dangerous, M. Leroy is undecided.

URINE IN TYPHOID FEVER.

M. Martin Solon lectured on the state of the urine in typhoid fever, his conclusions were as follows:—1. The urine is less abundant, of a high colour, and more dense than in health, it is almost always acid. 2. Alkalinity of the urine is rare; nevertheless, in typhoid fever, the urine quickly passes into the alkaline state, from the superabundant quantity of urea contained in it. This quantity is sometimes so considerable that it is possible to obtain crystals of the nitrate of urea without previous evaporation. 3. Though habitually clear, the urine of typhoid patients sometimes exhibits a mucous cloud. 4. The clear urine sometimes remains unchanged under nitric acid, at others a slight cloudiness is produced. 5. This cloud is formed of the bi-urate of ammonia, and is seen at certain periods of fever, especially towards the crisis. 6. The bile undergoes a sensible change during the progress of fever, which change is doubtless the cause of the appearance of *bili-verdine* in the urine. 7. Albuminuria is a frequent temporary phenomenon in fever; and generally indicates a severe case. 8. Much advantage to prognosis and treatment may accrue from the inspection of the urine in fever.

COXO-FEMORAL DISARTICULATION.

An instance of this operation under the influence of æther was reported by M. Heurt. The operation was rendered necessary for the removal of an immense exostosis, and was performed without the least suffering. Considerable hæmorrhage occurred from insufficient compression of the vessels, but the man ultimately recovered.

STERILITY AND DYSMENORRHŒA.

M. Raynard presented a memoir on this subject, of which the following *resumé* is given:—

1. The cavity of the neck of the womb may be the seat of stricture, congenital or accidental, which is to a certain extent analogous to strictures of the urethra. 2. These modifications in the structure of the uterus induce serious disturbances in its functions, rendering menstruation and conception painful; and when occlusion is complete, impossible. 3. This state of the uterine neck is generally indicated by a thick white viscid discharge. 4. This condition, by keeping up continued uterine congestion, may give rise to serious organic disease. 5. Stricture of the uterine neck may be suspected in cases of dysmenorrhœa and sterility, which cannot be otherwise accounted for. 6. The treatment of urethral stricture is equally applicable to that of the uterine neck. 7. The best treatment consists in the introduction of graduated bougies, by means of the speculum, and allowing them to remain for an hour or two. 8. If this should fail, we must have recourse to incision of the neck.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DES SCIENCES, PARIS.

CHLOROFORM.

Numerous communications on the subject of chloroform have been received, but of those which relate to instances of operation, we shall give no account, as they can have little interest for the British reader. Respecting the physiological action of the vapour, M. Gerdy has arrived at the following conclusions :—

1. Chloroform, like æther, may excite cough, but it does so in a less degree. 2. If it touches the nose and mouth, it gives rise to an erythematic eruption. 3. Chloroform increases the salivary secretion, but less so than æther. 4. Chloroform with some persons nauseates more readily than æther. 6. The insensibility from chloroform is more prompt than that from æther.

MM. Tessier and Devasse read a paper in opposition to the mercurial treatment of fever, as recommended by M. Serres.

VESICO-VAGINAL FISTULA.

M. Jobert narrated four new cases in which this deformity was remedied by his method of *autoplastie par glissement*. They were all successful.

DETECTION OF ARSENIC.

M. Tizot recommends that all arsenic should be mixed with red sulphuret of mercury, colocynth in powder, and creosote; by this means colour, taste, and smell would all combine to render its detection easy when mingled with alimentary substances.

ON RETROVERSION AND RETROFLEXION OF THE UNIMPREGNATED UTERUS. ITS DISCOVERY AND TREATMENT.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

The subject of retroversion and retroflexion of the unimpregnated uterus is at present exciting considerable interest in the profession, and the comparatively recent doctrines regarding their frequency and the modes of diagnosing and of treating them are obtaining that place and confidence which a proper study of them must necessarily command. It is, therefore, at once interesting and important to the profession that correct views should be entertained and circulated, in regard to every point in their history. My object in the present letter is to point out in few words, that it is to Professor Simpson, of Edinburgh, that we are indebted for first stating accurately and settling the question of their frequency, and that it is to him solely that we owe those great improvements in the diagnosis and treatment of these displacements, and of other uterine affections, which have already done so much for our knowledge of the pathology of many of the diseases of females.

In a paper on retroflexion of the uterus in the last number of your *Journal* Mr. Hensley, while he properly acknowledges the advantages derived from the use of Professor Simpson's uterine sound, yet seems to think that the credit of discovering by means of it, the great frequency of versions and flexions of the uterus is due to Dr. P. Smith and Dr. Rigby. "Dr. Simpson, of Edinburgh," says Mr. Hensley, "has for some years been carrying on his researches on this subject. In 1844, Dr. Protheroe Smith first made out the existence of this displacement in a patient at the hospital for women; and since that time, both Dr. Protheroe Smith and Dr. Rigby have met with numerous cases in practice, and have proved that the disease is of far more frequent occurrence than is generally supposed, and much more frequent in the unimpregnated state than retroversion in the pregnant." Now, I am not aware that Dr. Simpson has as yet published at length any papers upon the special subject of retroversion and retroflexion of the uterus. But on April 19, 1843, in reading some lengthened communications to the Medico-Chirurgical Society of Edinburgh, on the subject of uterine diagnosis, he took occasion to make some remarks on these displacements of the womb, and pointed out the new means of diagnosis he had discovered for them, insisted on their great frequency, and at the same time laid down the manner of their treatment. I shall quote his own remarks from the report of the Society's proceedings, as published in the *Monthly Journal of Medical Science* for July, 1843, (p. 660)

"As one of the most important of all its (the uterine bougie,) applications, Dr. Simpson demonstrated that the uterine bougie, by shewing the *direction* of the uterine cavity, and hence of the uterus itself, and by its enabling us when it is introduced, to change at will the position of the organ, afforded a simple means of detecting those *displacements* of the unimpregnated uterus, known by the names of retroversion and retroflexion, anteversion and anteflexion,—states that Dr. Simpson further shewed were *very common*, and which, from the want of any proper means of diagnosis, had been almost constantly mistaken for fibrous, carcinomatous and other tumours situated bet ween the uterus and rectum, or between the uterus and bladder."

"In cases of retroflexion and anteflexion of the unimpregnated uterus, the organ can with facility be temporarily restored to its normal position and relations by turning the uterine bougie, when used as a means of diagnosis. Dr. Simpson proposed to maintain and fix the bougie in the uterine cavity for a length of time, as a means of cure. He laid before the Society a number of utero-vaginal pessaries, which had been used by him for this purpose. They were constructed of nickel and silver wire, and had each attached to them a part, which passed up to the fundus uteri. Some of them had been worn for weeks and months in the uterine cavity, and had produced little or no irritation."

If any doubt can be entertained as to the question of the priority of Dr. Simpson's investigations to those of Dr. Protheroe Smith and Dr. Rigby, it will suffice to settle the point, to quote Dr. Protheroe Smith's own words. "Professor Simpson's laborious inquiries and investigations (says he, Obstetric Record, No. I., p. 36,) have opened a path to modern discoveries and improvements in the mode of *examination* and *treatment* of the maladies of the uterus, and *to him we are indebted for shewing the frequency of the disease* of which I am about to treat."——"During a visit to Edinburgh, in the autumn of 1844, he called my attention to the fact that these affections are of common occurrence; since that, experience has proved to me the correctness of his opinion."

My object in this letter has not been to derogate in the slightest degree, from the honour which is due to

Drs. Smith and Rigby for *spreading* among the members of the profession, correct views in regard to the maladies in question, but simply and for the sake of justice to rectify an erroneous impression which seems to prevail in regard to the history of these important diseases. And I doubt not that Mr. Hensley will feel obliged to me for the few observations I have made.

I am, Sir, yours faithfully,

JAMES DUNCAN, M.D

53, Frederick Street, Edinburgh,
January 22, 1848.

PERIOD OF PUBERTY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I should feel greatly obliged if you would favour me by the insertion, in an early number of the *Provincial Medical and Surgical Journal*, of the following brief observations in reference to a passage which occurs in your notice of my work "On the Causes and Treatment of Abortion and Sterility, &c," in the number of your periodical, dated the 20th of October last.

In commenting upon that part of the volume which relates to the first appearance of the menses, you say,—"The researches of Mr. Roberton on this subject are well known, but the conclusions at which he has arrived do not seem to be borne out by the investigations of Mr. Whitehead." The disparity here alluded to, involving two principal points in the statistics of female puberty, namely,—1st, as respects the average age of puberty in England; 2nd, as to the numerical proportion of females in whom puberty became developed before the age of eleven years, is contained in the following passage of my treatise:—"But the results obtained by Mr. Roberton, respecting the age of the first menstrual crisis in this country, and those recorded by myself in the preceding tables, exhibit a difference of about nine months. This disparity I can account for only on the supposition that his inquiries may possibly include a greater proportion of educated females than mine; the menstrual advent taking place, as was already shown, considerably earlier in these than among the labouring and uneducated classes. It appears also, from Mr. Roberton's report, that the per centage of instances of puberty in this climate occurring before the age of eleven years, amounted to 3.15; while those happening in a corresponding period in my own records do not exceed 0.225 per cent."

In forming the above comparison, my antagonistic data were derived from a table introduced into Mr. Roberton's paper published in the 66th volume of the *Edinburgh Medical and Surgical Journal*, page 60, in which it is stated, from the evidence of 540 instances, that the average age of puberty in England, is fourteen years and ten months. It appears, however, from a foot-note subpended to the said table, (which I am sorry was formerly overlooked,) that this number, (540,) was "reduced, in order to a more accurate comparison between England and India, from the table of 2169 instances, [embodying Mr. Roberton's personal enquiries, and those of Professor Murphy, of Dublin,] for England, given in a former paper."

Perhaps it may with some reason be remarked in this place, that statistical evidence derived from among the Irish in reference to this subject, cannot fairly be adduced in support of the average for England, since, whatever influence early sexual intercourse may have in promoting a precocious development of the sexual organs, has its full effect in the sister island; as no restriction, either conventional or legal, exists to prevent the earliest practicable connubial alliances among the lower orders. Even among the poor Irish families, (of the Romish faith,) resident in the town of Manchester, marriages are consummated much earlier than among our own peasantry, and in many instances, as regards the female, these frequently take place before the change of puberty has been effected.

Mr. Roberton's own table of 450 cases, obtained from inquiries made in this town, gives, as the average age of puberty, 15.373 years. This very nearly corresponds to my own, which is 15.565 years. But if Mr. Roberton's be compared with my first group, (Table II.,) the numbers are identical.

With reference to the second portion,—namely, the numerical proportion of females arriving at the age of puberty before eleven, Mr. Roberton's deductions have also evidently been exaggerated by the same combination of his cases with those of Professor Murphy. He says, at page 61 of the Journal already alluded to, "I find that the per centage under eleven is, for England, 3.15." This ought to be for England and Ireland. In Mr. Roberton's own table, the number given for those who accomplished the change in the eleventh year, is ten, affording a per centage of only 2.22.

I am the more anxious to make these corrections, as the passage alluded to on this subject in my treatise has since been quoted in the *Edinburgh Medical and Surgical Journal*, and also in the *British and Foreign Medico-Chirurgical Review*, the latter being accompanied by a remark of the reviewer, which might possibly be construed to Mr. Roberton's disadvantage.

Yours very respectfully,

J. WHITEHEAD.

Oxford Street, Manchester,
January 13, 1848.

General Retrospect.

ANATOMY.

GANGLIONIC CHARACTER OF THE ARACHNOID MEMBRANE.

The serous investment of the brain, has hitherto been considered solely in the light of a contrivance by which the integrity of the cerebral functions are maintained during any temporary change which may take place in the quantity of the circulating fluid, it has, however, been recently ascertained by Mr. Rainey, that it serves a further use, as a medium from which the ultimate fibres of the sympathetic system are distributed to the cerebral vessels. The first idea which the

author conceived of the sympathetic character of the arachnoid, was from seeing a number of cords between the arachnoid and pia mater, and ramifying equally on both; the twigs supplying the former being further observed to be lost in certain minute corpuscles, in which the membrane abounded. Having satisfied himself that the above cords were in reality derived from the sympathetic system, by comparing them microscopically with other portions of that system, the author concludes that they in fact arise from the membrane itself, which stands to them in the relation of a ganglion or plexus, and is analogous to other plexuses of the same system. It must be observed, however, that the author does not consider the whole membrane to be nervous, but that this property resides chiefly in those parts which he describes as made up of a soft corpusclar matter similar to that which is seen in the true ganglia of the sympathetic.—*Medical Gazette.*

MINUTE STRUCTURE OF THE LUNGS.

Mr. Rainey, in an interesting commmunication to the Royal Medico-Chirurgical Society, gives an account of the minute anatomy of the lungs, of which the following summary includes the principal points of interest:—

1. With respect to the bronchial tubes, these are, for the greater part of their course, cartilaginous; but that at a certain distance from the surface, the cartilaginous rings are lost, and the canal is continued by the lining membrane alone. Having arrived about one-eighth of an inch from the surface, this membrane also becomes deficient, and the air passages then appear to be formed solely by the air-cells between which they pass. They are then termed intercellular passages.

The membrane of the bronchial tubes is supplied by a distinct set of blood-vessels, which at the abrupt termination of the membrane anastome with those of the air-cells. The intercellular passages are at first circular, and like the tubes of which they are a continuation, do not at first communicate with many air-cells; the communication, however, is very free towards the peripheral destination of the canal. A remarkable anatomical fact, announced by Mr. Rainey, is, that the mucous lining of the bronchial tube does not, as is generally supposed, continue along the intercellular spaces, and into the air-cells, a circumstance which, as he justly observes, sufficiently explains the different effects of inflammation of the tubes and of the air-cells; the latter, which are lined by fibro-cellular tissue, being accompanied by the deposition of fibrin instead of mucus.

2. The air-cells open upon the bronchial tubes and intercellular passages by well-defined circular apertures, surrounded by a ring of fibres, and a dense plexus of capillary vessels. These vessels, in the lungs of mammals, run between two layers of the pulmonary membrane, so that there is but one vascular network between two given cells, and the blood is aerated on each side. In the lung of the frog, serpent, &c., there are two plexuses between any two cells. Mr. Rainey concludes, in opposition to Dr. Addison, (of Malvern,) that the fœtus prior to the act of respiration possesses fully-formed air-cells, which are also surrounded by capillary plexuses.

PHYSIOLOGY.

USE OF GLISSON'S CAPSULE.

M. Petrequin suggests what seems a probable explanation of at least part of the purpose served by that continuation of the *tunica propria* of the liver to which the name of Glisson's capsule is applied, and which accompanies the branches of the portal vein, hepatic artery, and biliary duct, along their ramifications through the substance of the liver. He regards it as destined to facilitate the portal circulation, explaining his view in the following manner:—The liver is a compact organ, not readily admitting of being distended; there is no heart to impel the blood through the vena portæ, nor are there any valves to sustain the column of blood in it; the capacity of this vein is also greater than that of the mesenteric artery to which it corresponds, and it is one of the vessels whose calibre is most variable, because, from its relation to the digestive organs, it must admit of dilatation when fluids are absorbed, and be enabled to contract when those fluids have passed off. These various obstacles to the portal circulation are counteracted, and the power of accommodating the capacity of the vessel to its contents is insured, by its running in a fibrous sheath, and being quite independent of the tissue of the liver; it can dilate or contract as the quantity of fluid traversing it increases or diminishes, and it can also contract so as to press on the blood it contains, and thus favour its circulation.—*British and Foreign Medical Review.*

PRACTICAL MEDICINE.

TREATMENT OF CEREBRAL INFLAMMATION.

Mr. Solly says, in the treatment of these affections the following principles must be attended to:—1. There is no time to be lost, even minutes are of value. 2. Inflammation of the brain being a depressing disease, general blood-letting is not often admissible. 3. Though this may be attended with benefit at the time, the good derived is seldom permanent. 4. Local blood-letting by leeches and cupping is generally useful, and especially in cases of insomnolescence, arising from abnormal action of the brain. 5. In cases of insanity, where opium has failed to produce sleep, leeches and cold applications generally will; and, if they do not, it is strong evidence that the excitement arises from hyperæmia, and not from anæmia, as in that of delirium tremens. 6. Aconite and digitalis are the best sedatives, especially when combined with mercury. 7. When it is advisable to salivate rapidly, raise the cuticle by boiling water, or a similar escharotic, and dress the surface with strong mercurial ointment. 8. Always commence the treatment with a brisk mercurial purgative. 9. Soothe the patient's feelings in every way. 10. Never leave anything that is disagreeable to the patient to be done by a nurse or attendant, such as the application of leeches &c., but persuade him to have them applied. 11. Never lose your patient in the treatment of a chronic case, or try to hasten the cure by increasing the doses. 12. When it is considered

necessary to continue the use of mercury for a lengthened period, combine tonics with it.—*Medical Times.*

THE ACTUAL CAUTERY IN NEURALGIA.

M. Notta adduces thirteen cases in illustration of the value of this form of counter-irritation. Of these two were instances of intercostal neuralgia, ten of sciatica, one of facial neuralgia. Half the patients were robust, the remainder debilitated and impoverished. All were well-marked instances of neuralgia,—that is to say, there were points painful on pressure, and darting pains along the course of the nerves; these pains were severe, and sleep was more or less disturbed in all the patients. Of the patients labouring under sciatica, six were quite unable to walk, and four only had received any benefit from previous treatment. In all these cases the cauterization was conducted, as follows:—The patient being placed in a favourable position, was rendered insensible by ætherization, and the affected part was crossed two, three, or more times, with a thin iron, heated to whiteness, after which it was covered by compresses, dipped in cold water. The cautery produced brownish lines, which the day after became dry and crisp, and eventually desquamated. The subsequent pain was inconsiderable.

In respect of the effects of the cauterization, it may be stated that the most remarkable was the notable relief of the neuralgic pain. In five or six hours the limb could be moved with facility, and the following night was tranquil; in the course of twenty-four or forty-eight hours the darting pains disappeared. Of the thirteen patients, in whom it was tried, ten were perfectly cured, two were much relieved, and in one only was there no improvement.—*Union Médicale*, Oct., 1847.

CHLOROFORM IN ASTHMA.

Mr. Chandler has tried this remedy in the following instance:—

The patient, a lady, aged fifty-six, having had the prevailing influenza, for which leeches had been applied to the chest, was seized with her old complaint,—the pain, exceedingly acute, referred to the chest and epigastrium, darting through the body to the back. A free inspiration could not be taken, nor the recumbent posture for a moment endured, but from nine o'clock in the morning of the 6th, to half-past twelve o'clock on the 7th, the hours passed with this patient sitting erect in bed, almost gasping for breath, and uttering a low moaning cry, with every now and then loud shrieks from the sense of constriction on the stomach becoming more acute. Having a fortnight previous to this taken sixteen ounces of blood from her, I was very reluctant to bleed again, and resolved to give the chloroform a trial. I accordingly poured half a drachm on a sponge, hollowed to fit the mouth and nostrils, and held it at first close to, but not touching, the face. In less than half a minute she became excited, waving the arms about, and uttering incoherent expressions, accompanied with loud hysterical laughter; her prevailing idea seemed to be, that she was 'riding on a moonbeam.' I then placed the sponge in contact with the face, when the limbs gradually relaxed, the arms dropping on the bed, quivering of the eyelids and twitching of the muscles of the face took place, and she fell back on the pillow, drawing deep and prolonged inspirations, between each of which, perhaps, eight could be counted. I now withdrew the sponge, opening the curtains to admit air. Respiration gradually became more regular, and she lay without motion, the body well thrown back on the bed, not the slightest vestige of spasm remaining. This state continued until four o'clock, the patient apparently half sleeping, conscious of what was passing in the room, when she sat up and took some food, describing her sensations as having been exceedingly pleasurable. Shortly afterwards she enjoyed a quiet sleep of some hours' duration, and the following morning she was quite quiet, no return of spasm, and no ill effect from inhalation: she is now comparatively well. I tried the vapour of sulphuric æther in this case, some time ago, not only without success, but with much increase of the sufferings of the patient.—*Medical Gazette.*

ACETATE OF LEAD IN TYMPANITES.

Dr. Badeley, mentions a case of temporary intestinal obstruction with excesssive lymphactic distension, in which the best effects followed the exhibition of the acetate of lead. Purgatives had failed to procure an evacuation. Vomiting supervened, with hiccough, and the coils of distended bowels could be felt through the abdomen. Feeling convinced, that the symptoms depended upon a loss of tone in the muscular fibres of the alimentary canal, alum was ordered, with turpentine injections, and having failed, three grains of the acetate of lead, with one-sixth of a grain of morphia, were given every four hours. This was soon followed by the expulsion of large quantities of gas, and copious dejections. The hiccough and vomiting declined, and the man was soon convalescent.—*Lancet*, Jan. 8th.

USE OF ICE IN EXHAUSTING DISEASES.

Some interesting cases are quoted in a recent number of the *Revue Médico-Chirurgicale*, from a French journal, in which ice taken internally seemed to be of great service in reviving powers fast sinking. The writer employs it in very various diseased conditions, providing these manifest the signs of intense debility. The re-action it induces may prove curative in some cases, while in others, in which this is impossible, a marked temporary amelioration of the patient's state occurs. In the cases in question there is great atony and extenuation, and an extreme aversion to any food whatever, with or without a development of heat. A number of morbid states and organic lesions, having no other points in common, may induce this condition. Iced water does not succeed anything like so well as the administration of the ice in little lumps, which by requiring time for their solution, ensure its gradual introduction. These impart great tone to the system, and revive the inclination for food in a remarkable manner.—*Rev. Méd.-Chir.*, Vol. 2, p. 168.

SURGERY.

LUXATION AND FRACTURE OF THE CLAVICLE.

Luxations of the clavicles are nearly equal in number at each end of the bone. There are cases in which the muscles have much to do with the treatment, and

this consists in placing the parts in such a position that the muscles concerned may be sustained in their ordinary state of association. My practice is to avoid all bandages, which only excite the muscles to undue action. All I do is to place the patient on his back in a flat bed, and the bones immediately recede into their proper position, and are uninterruptedly kept so. The arms should be kept as quiet as possible. The displacement at the acromial end is less than at the other, when luxated, because it is retained nearly in its place by the trapezoid and conoid ligaments. This case requires less attention and time than that of the sternal end, where much more and longer quietude is necessary. The principle upon which this method is adopted, is that of keeping the muscles in their natural order and power of acting.

Fractures of the clavicle occasionally occur so near the acromial point, that it is difficult to determine whether they are not luxations. I treat all fractures of the clavicle by merely placing the patients on flat beds; bandages seem commonly to do little good, and are not required if the patient will keep his bed. The clavicle is a bone which quickly unites.

Infants are frequently brought to me, in whom, by some accident, the clavicle has been only bent, and not completely separated by fracture. This bone suffers in very young children readily when they fall from small heights, or from the mother's lap, and the injury is often not adverted to, and only discovered on dressing the child. The best bandage is a handkerchief bound round in a figure of eight form, and a sling. The deformity quickly disappears.—*Observations on some parts of Surgical Practice, by Mr. Vincent.*

FRACTURE OF THE CLAVICLE.

Very unnecessary fears have arisen from the bone uniting not quite regularly. It is true it cannot always be effected without some slight deformity, but this is of no consequence in men, and even in women is only seen in such as are of spare make. This need not take place when the fracture is situated in the external third of the bone, the fragments being maintained *in situ* by the ligaments and muscles, so that a bandage is not even necessarily required. When the fracture occurs within the inner two-thirds, there is always some displacement in the adult, although this does not take place in very young children. The most complex apparatus are in nowise preferable to the following simple plan of treatment:—A bandage is carried from the armpit of the sound side across the back and shoulder to the fractured clavicle. The patient's hand is brought up to the sound acromion, so as to raise the elbow as high as the sternum, the shoulder being thrown backwards and upwards. Whilst an assistant holds the limb, the bandage is repeatedly passed over the anterior part of the arm, and brought round by the sound arm pit; and over this is passed one well moistened with dextrine, so as to produce an inflexible mould. The bandage need not be put on for four or five days after the accident, and in from a week to a fortnight the fracture will be sufficiently firm to allow of its removal. It is an error to suppose that a patient cannot raise his arm to his head when his clavicle is fractured. He believes he cannot, and is prevented from trying by the pain this causes. But if you insist upon it, and that not doubtingly, you will find he can accomplish it. I have not seen six exceptions in twenty years.—M. Velpeau, *Gazette des Hôpitavx*, No. 115.

SOLUTION OF SULPHATE OF IRON IN PROLAPSUS ANI.

Mr. Vincent states that he has of late had great advantage in employing a solution of sulphate of iron, one grain to the ounce, in prolapsed bowels, and that an operation may often be dispensed with, and the patient cured merely by the use of this remedy. Very lately he has had two cases of the worst sort, one of twenty years' standing, with great protrusion and abundance of bleeding piles, which in three weeks was completely cured. The other came from one of the institutions which offer great pretensions in the treatment of these cases. The patient was very bad, having both internaland external piles, and the bowel descended largely and most readily; he was completely relieved in about a month. Other cases of a slighter kind have been set to rights in a week. The patient should be kept in bed, so that the bowel may be as much as possible in repose, and after it is cleansed out, a small quantity of the injection should be daily thrown up, and retained. Balsams are also well adapted to the disease.—*Observations on Surgical Practice*, p. 174.

Medical Intelligence.

TRIBUTE TO DR. FORBES.

The following just tribute of honour is rendered to our esteemed associate Dr. Forbes, by the Editor of the *Archives Générales de Médecine*:—

After twelve years of a dignified and honourable existence, one of the most distinguished British medical journals has ceased to exist. In a well-conceived and well-written *adieu*, Dr. Forbes, the editor, has laid before his readers the causes which have prevented the success of his enterprise. We have frequently had occasion to appreciate the scientific spirit, the exactitude and impartiality with which the "British and Foreign Medical Review" was conducted, and willingly accord the editor our tribute of praise and regret. Some courage was required thus to sacrifice the best years of a life, and a portion of a fortune, in the attempt to perfect so difficult an undertaking. Dr. Forbes attributes his failure to the multiplicity of Journals, which have increased in a ratio disproportionate to the number of readers; and it is but too true that many of the best-established and most reputable medical men never open a medical book of any kind, still less a medical journal. We fully sympathise with him in these and his other reasons. Doubtless, in taking high ground in noticing only really scientific productions, in refusing communications bare of interest and common place, he soared far above the comprehension of the more grovelling minds around him, and was little in accordance with that spirit of industrialism, which in England as in France, speculates upon ignorance and routinism.

APPOINTMENTS.

Dr. Meyer has been appointed Private Physician to H.R.H. Prince Albert.

Charles Aston Key, Esq., has been elected President, and C. J. B. Williams, M.D., and John Dalrymple, Esq., Vice-Presidents, of the Pathological Society, of London, for the year 1848.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members Friday, Jan. 14th :—B. Mallam; H. H. Brown; G. Keer; P. S. Warren; C. Johnson; J. Robinson; D. Williams; F. King; H. Davis; C. Morgan; A. Adams.

HUNTERIAN ORATION.

The Hunterian Oration will be delivered on Monday, February 14th, by R. D. Grainger, Esq., Lecturer on Physiology at St. Thomas's Hospital.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, January 6th:—David Evans, Llanfyllin, Montgomeryshire; Walter Winter Walter, Stoke-under-Ham, Yeovil; Percival Thomas Meggs, Alverstoke, Hants; Thomas Henry Mitchell, Kington.

Gentlemen admitted Licentiates, Thursday, January 13th:—Thomas Carr Jackson, Clitheroe; Wm. Henry Ackland, Bideford; Robert Rayner, Birstal, Yorkshire.

OBITUARY.

Died, December 14th, 1847, at Florence, aged 67, Sir James Annesley, F.R.S., F.A.S., &c., late of the Hon. East India Company's Medical Service, and well-known for his truly valuable works on the Diseases of India, and Warm Climates.

December 28th, at Atherston, aged 89, John Power, M.D.

January 2nd, 1848, at Carlow, aged 83, Martin Tuomy, M.D., formerly Professor of the Practice of Medicine in Trinity College, Dublin.

January 4th, at Shefford, Bedfordshire, aged 73, Charles Seaman Gaye, Esq., M.R.C.S.

January 9th, at Armagh, of fever, Thomas S. Parker, M.D.

January 12th, at Brecon, aged 65, of fever, Thomas Batt, Esq., Coroner for the County of Brecon, Senior Surgeon to the County Infirmary, and Surgeon to the County Gaol.

Lately, at Tipperary, of fever, Edward Dalton, M.D., Medical Attendant of the Bansha Dispensary.

Lately, at York, William Stephenson Clark, Esq., M.R.C.S.

INQUIRY INTO THE MEDICINAL ACTION OF ARSENIC.

NOTICE TO MEMBERS.

Mr. Hunt, of Herne Bay, requests us to acknowledge the receipt of many interesting communications from members of the Association, in reference to their experience in the medicinal use of *arsenic*, embodying records of nearly 2000 cases. As a large majority of the members have not as yet responded, and as the silence of many may be in some measure accounted for by the urgent nature of their engagements during the present sickly season, it is proposed to keep open the enquiry till the *end of March*, by which time it is hoped that every member, however limited his experience, will have responded to the questions addressed to them in the Journal for Dec. 1st, 1847, page 662. Those who have the charge of hospital records especially are earnestly requested to forward, (in a tabular form,) a report of the cases in which arsenic has been administered.

TO CORRESPONDENTS.

Communications have been received from Mr. T. Hunt; Mr. Whitehead; Mr. Crompton; H. B. B.; Mr. H. S. Smith; The Birmingham Pathological Society; Mr. T. B. Torr; Mr. S. Miller; Dr. Oke; Professor Simpson; Dr. Kennion; Dr. J. Duncan.

A Student.—Mr. Wilson's Anatomist's Vade Mecum will probably answer the purpose. No edition of the London Pharmacopœia has been published since 1836, but a new one may be expected during the course of the present year.

MEDICAL & SURGICAL JOURNAL.

MEMOIR ON TURNING, AS AN ALTERNATIVE FOR CRANIOTOMY AND THE LONG FORCEPS, IN DEFORMITY OF THE BRIM OF THE PELVIS, &c. &c.*

By J. Y. Simpson, M.D.,
Professor of Midwifery in the University of Edinburgh.

Sect. IV.—The Duration, and consequently the Danger, of the Labour is decreased by the Proposed Practice.

In the short summary which I gave in January last of the advantages of turning over embryulcio, I stated one strong reason in favour of delivery by the alternate operation to be this,—"*that it was more safe to the mother, because it could be performed earlier in the labour, and more speedily,*"† than craniotomy, or the application of the long forceps. And I have the most sincere belief that the practice I propose may be the means of saving much, both of maternal and infantile life, by enabling us in some cases to abridge the mere duration of a difficult labour, so that we may terminate in a few minutes a delivery, that, which under other plans of treatment, might still be protracted onwards for hours or even for days. At the same time I am fully aware that when I state my conviction that the mere degree of *duration* and continuance of a labour is, *per se*, dangerous both to the mother and child, and very often fatal even in its influence, I venture to broach a doctrine which stands up alike against the opinion and the practice of some of the highest authorities in the obstetric profession.

About half a century ago, when treating of the influence of the duration of labour in difficult and instrumental deliveries, Dr. Osborne observed,— "I believe it is confirmed by general observation, that women recover at least as well, after long, lingering, and laborious labours, the duration of which may have been extended to several days, as after the easiest, quickest, and most natural delivery."‡ In making this remark, Dr. Osborne stated not his own opinion only, but, I believe, the general opinion of the accoucheurs of his time; and the same doctrine little or not at all modified, still continues to be taught and acted upon, down to the present day, in the great English and Irish schools of midwifery, as the able and excellent writings of (for example,) Professors Davis and Murphy, in London, and Drs. Collins and Beatty, in Dublin, &c., fully testify.

That, *per se*, the duration of labour has no very direct nor decisive influence upon the degree of danger and fatality accompanying parturition, is a doctrine which probably originated in, and has been perpetuated by, an erroneous system of observation. In founding and supporting it, obstetricians have, I believe, drawn their deductions, not from the *whole* of their practice, but from *parts* only of it; they have not reckoned upon the certain results of their *general* collection of facts, but depended upon the fallacious results of isolated and *individual* instances; they have not, in short, counted up the terminations and consequences of *all* their protracted cases, but have relied upon the evidence of some *single* striking case or cases of perfect, and it may be, rapid, recovery after labour of a very prolonged duration. In proceeding thus, obstetric authors have not followed a course altogether different from that pursued in the study and investigation of many other similar questions in medical science and practice. For confessedly, the medical mind has ever been too apt to recollect and found upon those facts only which are in favour of any preconceived opinion or opinions it may chance to have adopted; and the cases of failure are too often forgotten amid the more agreeable remembrance of the cases of success. It is on this account that the numerical method of reasoning and investigation, by obliging us to count up *all* our cases, and *all* our results, whether good or bad,—whether instances of recovery or instances of death,—is no doubt destined to revolutionize, in a great degree, our modes of inquiry, particularly in surgery and midwifery, by imparting infinitely more precision and certainty to our present deductions and precepts where they are true, and shewing us in language that cannot be misunderstood, the erroneousness of our doctrines where they are not true.

The question of the duration of labour in relation to its effects upon the danger and mortality accompanying parturition will be found, in my humble opinion, to afford an apposite example of the truth of these remarks,—for when this question is examined, as it can alone properly be examined,—by the numerical or statistical method, the results that are thus yielded, assuredly directly gainsay and contradict the accredited

* Continued from page 5.
† "Monthly Journ. of Med. Science" March, 1847, p. 718.
‡ Essays on the Practice of Midwifery in Natural and Difficult Labours, p. 66,

impressions and common belief of the profession upon the subject. With the exception of Dr. Collins, of Dublin, few, or indeed no writers have, in their obstetric reports of hospital or private practice, furnished us with data shewing the duration of labour either in their natural or in their operative cases of midwifery. In his "Practical Treatise on Midwifery," (a work, the great value and candour of the facts contained in which it would be difficult to overpraise,) Dr. Collins has given the result of the cases which occurred in the Dublin Lying-in Hospital during a period of seven years, commencing November, 1826, and he has published throughout the work, and especially at the end of its individual chapters, tables, and data, from which the duration of the labour in most cases and complications can easily be calculated and compared. I shall state briefly some of the results regarding the influence of the duration of labour which I have obtained by summing and counting up the individual facts and data which Dr. Collins has published. And the results which I have in this way obtained, will, no doubt, be regarded by some as the more valuable and trustworthy, seeing that the data from which they are calculated have been collated by Dr. Collins, and given by him to the world under the generally prevailing idea that the mere length of the labour was no guide or test of its danger or mortality.

During the seven years that Dr. Collins had charge of the Dublin Lying-in Hospital, 16,414 women were delivered in it; and of these 164 died, or one in every 100 of the mothers was lost. In 15,850 of these cases the duration of the labour has been marked and published; in 1 in 29 only was it not noted. Out of the 164 fatal cases, in 138 the duration of the labour has been marked and published; in 1 in 6 it was not noted. Now, if in relation to the duration of labour as bearing upon the maternal mortality, we calculate the proportion of the 138 maternal to the whole, 15,850 labours, I find that the interesting result is that which is shewn in the following table. Let me merely premise that the table reads as follows:—Out of all the women delivered within one hour, 1 in 322 died; out of all those in whom the labour continued from two to three hours, 1 in 231 died; and so on.

TABLE II.

Shewing the Proportion of Maternal Deaths in relation to the Duration of Labour in 15,850 *cases of Delivery.*

Duration of Labour.	*Proportion of Mothers Lost.*
Within 1 hour	One in 322 died
From 2 to 3 hours	„ in 231 „
From 4 to 6 „	„ in 134 „
From 7 to 12 „	„ in 80 „
From 13 to 24	„ in 26 „
From 25 to 36 „	„ in 17 „
Above 36 hours	„ in 6 „

The preceding table affords ample evidence that, contrary to the general opinion of the obstetric profession, the mere length of the labour is a most serious and important element in reference to the degree of danger and fatality accompanying the process. For, in fact, as shewn by these calculations "*the mortality attendant upon parturition increases in a ratio progressive with the increased duration of the labour.*" And this does not hold true with regard to the life of the mother alone. It equally holds true with regard to the life of the infant. For, exactly in the same way, as proved from the same collection of data, I find also that as a general fact "*the infantile mortality attendant upon parturition increases in a ratio progressive with the increased duration of the labour.*" Dr. Collins reports 1121 children as having been still-born. In 1045 of these cases the duration of the labour was noted. The following table shows the proportion of the children lost in labours of different degrees of duration. Like the preceding table, it reads thus:—Out of all the women delivered within two hours one in 20 of the children was lost; out of all the women whose labour endured from three to six hours, one in 18 of the children was lost; and so on.

TABLE III.

Shewing the Proportion of Infantile Deaths in relation to the Duration of Labour in 15,850 *cases of Delivery.*

Duration of Labour.	*Number of Infants still-born.*
From 1 to 2 hours	One in 20 was lost
„ 3 to 6 „	„ in 18 „
„ 7 to 12 „	„ in 11 „
„ 13 to 24 „	„ in 6 „
„ 25 to 36 „	„ in 3 „
Above 36 „	„ in 2 „

The two preceding tables refer to the proportion of maternal and infantile deaths as regulated by the duration of the labour. But many morbid complications and accidents may arise during parturition without necessarily proving fatal either to the mother or infant. The occurrence, however, of these complications and accidents is regulated by the same law of duration as I have above shown to regulate the actual deaths of the mothers and children. For, exactly in the same way, it may be laid down as a general proposition, that "*the mortality of most of the morbid complications connected with labour increases in proportion as the labour is increased in its duration.*" It would be easy to demonstrate for instance, that this holds good with regard to various obstetric complications taken individually—such as convulsions, rupture of the uterus, retention of the placenta, or hæmorrhage before and after its removal, puerperal fevers, puerperal inflammations, &c. The liability to each one of these complications and results certainly increases with the length

of the process of parturition. But, it may be enough for my present purpose to shew that taking these complications collectively, such is the result: the tendency to their general occurrence becomes greater and greater in proportion as the length of the labour is allowed to become greater and greater.

In his Treatise, Dr. Collins has recorded the duration of the labour in twenty-four cases of puerperal convulsions; in twenty-four cases of rupture of the uterus and vagina; in sixty-two cases of retention of the placenta; in 102 cases during and after the third stage of labour; in eighty-four cases of puerperal fever; in five cases of fatal pelvic abscess; and in five fatal cases of inflammation and sloughing of the vagina; in all 306 cases of complication occurring in 296 patients. The following table shews the proportion in which these 306 complications occurred in labours of different durations. It reads thus :—Of all the women who were delivered within one hour after the commencement of labour, one in 114 suffered from one or other of these obstetric complications; of all those whose labours were prolonged from one to two hours, one in 90 suffered from one or other of these complications, and so on.

TABLE IV.

Shewing the Proportion in which 305 *Morbid Complications occurred in* 15,850, *Labours of different Durations.*

Duration of Labour.	*Proportion of Complications:*
Within 1 hour	One in 114 was complicated
From 1 to 2 hours	„ in 90 „
„ 2 to 3 „	„ in 69 „
„ 4 to 6 „	„ in 58 „
„ 7 to 12 „	„ in 32 „
„ 13 to 24 „	„ in 12 „
„ 25 to 36 „	„ in 9 „
Above 36 hours	„ in 5 „

The evidence which I have adduced in the preceding tables, affords ample proof that the proportion of maternal and infantile deaths, and of obstetric complications, becomes, as a *general law* gradually more and more numerous as the process of labour becomes more and more prolonged in its duration. But I have brought forward the facts principally for the purpose of shewing that out of them, and in connection with them, there is deducible another all-important principle, in reference to a practical and obstetric operative inquiry of the present nature,—viz., that when operative interference, such as the forceps, crotchet, turning, &c., is required, in order to terminate a difficult and morbid labour, the *time* of the labour at which that interference is had recourse to, regulates the amount of attendant danger much more than the details and effects of the operation itself. In other words, in accordance with the general law already illustrated, the extent of danger or fatality attendant upon operative and instrumental delivery, is regulated in a direct and demonstrable degree by the previous length of time allowed to elapse before the artificial interference is had recourse to; the resulting mortality increasing in amount according as the period at which the operation is performed is proportionally more distant from the date of the first commencement of the labour.

It is not in my power to prove from Dr. Collins' Treatise that this law holds true in regard to the alternative operation of delivery by the long forceps, for his work affords no data on this point. In fact, in instances in which the head of the child is arrested at the brim, he and the profession generally in Dublin, prefer the use of the perforator to the use of the long forceps; and during the course of the seven years throughout which his report extends, this latter instrument does not seem to have been employed once in the Dublin Hospital, while craniotomy was, during the same period, employed above eighty times. During these seven years, however, the short forceps were used to terminate the delivery in twenty-four patients in whom the head was sufficiently low down in the maternal passages; and perhaps the results in these twenty-four cases will be regarded as a sufficient illustration that in forceps' operations the general law holds good, that "*the operation is dangerous and fatal in proportion to the length of labour allowed to elapse before the artificial delivery is practised.*"

TABLE V.

Shewing the Maternal Mortality attendant upon 24 *Forceps-Operations, to be regulated by the previous Degree of Duration of the Labour.*

Date of Operation.	*Results to the Mothers:*
In labours terminated within 24 hours.	One out of 13 died*
In labours terminated in from 25 to 36 hrs.	„ „ 6 „
In labours terminated in from 37 to 48 hrs.	„ „ 4 „
In labours terminated in above 48 hours.	„ „ 2 „

Dr. Collins's data regarding the operation of craniotomy are more extensive, and hence more valuable. During the seven years included in his report, perforation of the head of the infant was practiced in

* In the single fatal case of forceps operation out of thirteen, in which the women were delivered before the labour had continued twenty-four hours, the mother became insensible after the pains had set in for a few hours, and the instruments were apparently used in consequence. The whole labour was only of eight hours duration. She died in three hours after delivery.

eighty-five cases in which there was extreme difficulty in the labour, or where the child was dead, and interference necessary for the patient's safety, or for the full completion of the delivery. In seventy-six out of these eighty-five cases, data are afforded for ascertaining the duration of the labour.

Out of the seventy-six women, fourteen, or one in every five and a half, died. The following table of the results of these seventy-six cases of craniotomy, as influenced by the previous duration of the labour, affords direct evidence of the proposition which I have already stated, that the fatality attendant upon this, as upon the other allied forms of forced or artificial delivery, is regulated by the date or period of the labour at which the operative interference is had recourse to.

TABLE VI.

Shewing the Maternal Mortality attendant upon 76 Craniotomy Operations, to be regulated by the previous Degree of Duration of the Labour.

Date of Operation.	*Results to the Mothers.*
Hours.	
In labours under 24	One out of 19 died
„ from 25 to 48	„ 8 „
„ above 48	„ 3 „

The preceding body of evidence might easily be rendered more minute and detailed if it were necessary. But I hold that it affords proofs sufficiently strong and direct for our present enquiry. And the important relations which it has to that inquiry amount to this, that the facts adduced demonstrate—

1st. That as a general law the amount and proportion of maternal and infantile deaths accompanying parturition are regulated and modified by the length and duration of the labour.

2nd. That the liability to various morbid obstetric complications during and after delivery is modified and regulated by the same law; and—

3rd. That the mortality attendant upon obstetric operations, such as the use of the forceps and crotchet, is also strictly modified and regulated by it,—operative delivery being more and more fatal in proportion to the lateness in the course of the labour at which it is adopted; and, on the other hand, less and less fatal in proportion to the earliness in the course of the labour at which it is practised.

Now, the object of the present memoir is to propose that in cases of arrestment of the head at the brim of the pelvis, artificial delivery should be accomplished by turning, instead of being accomplished by the long forceps or craniotomy. And the operation which I thus wish to substitute has, as I have stated at the commencement of this section, this great and high advantage over both the two others, for which I propose it as an alternative, that, *cæteris paribus*, delivery by turning can, and must, as a general rule, be practised far earlier in the labour, than delivery either by the long forceps or the crotchet; and in proportion as it is practised earlier, so far also will it be practised with greater safety and greater success. A few remarks upon the time at which the employment of the long forceps or perforator is usually adopted will render this deduction more evident. In our next communication we shall consider this point, and the value of auscultation in relation to operative delivery.

(To be continued.)

THE TAXIS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Your correspondent, "A Retired Surgeon of the Irish College," (*Provincial Journal*, 1847, p. 682,) deserves the thanks of the profession both for the courage with which he impugns the prevailing practice in the reduction of strangulated hernia, and for the perseverance with which he persists in calling attention to his own method, believing, as he evidently does, that its general adoption would prevent much suffering and save many lives. His sincerity and experience entitle his views to examination, and I gladly take the opportunity which is thus afforded, to call upon Hospital Surgeons, and those especially who are connected with the Association, to consider whether the prevailing method of using the taxis is the very best that can be adopted for the purpose.

It is much to be regretted that our lecturers and writers on surgery, too generally dwell with tedious minuteness on every step and stage of what is called "the operation" for strangulated hernia,—*i. e.*, the operation *with the knife*, while the far more difficult and delicate operation *without* the knife, the *taxis*, is passed over cursorily and carelessly as though its successful performance were dependent upon chance rather than science and skill. "The moment that you find the tumour is hard, incompressible, not yielding in the slightest degree; that there is *no gurgling*, no diminution of the convexity and hardness, not the slightest appearance of *getting the contents of the intestine out*, urge with all your eloquence the propriety of the operation, for there is little danger if the operation be performed at the proper time,—the greatest danger if it be delayed after a certain time." (*Med. Gaz.*, vol. xiij., p. 988.) These are the words of the lamented Sir Charles Bell, and they constitute a fair sample of the modern theory and practice of the London Hospitals. The late Sir Astley Cooper, who has left so splendid a contribution to the surgical anatomy of hernia, directs that the hernial tumour should be *kneaded by a successive motion of the finger and thumb*, "until you at last obtain a passage for a *small portion* of intestine or omentum through the strictured part." (*Cooper's Lectures.*) I agree with your correspondent that much of this is erroneous in theory and inefficient if not

mischievous in practice. The return of the hernia does not occur in the way described, nor is it the primary object of the taxis to "get the contents of the intestine out."

Strangulated hernia is an accident involving considerations, not mechanical only, but anatomical, physiological, and pathological. First, a portion of intestine is forced through the ring, together with a portion of omentum or mesentery, or both; the substance of the latter fills up the ring. Compression upon the veins is the next occurrence. The arteries, from their tone and elasticity, continue to pour blood into the tumour, which the veins cannot return, and the tumour increases in size from venous congestion, frequently without any further advance of intestine through the ring. This is the first stage of strangulation. In the second stage active inflammation ensues. In the third, sphacelus, produced either by the intensity of the inflammation, or more probably by the circulation in the tumour being at length wholly arrested by the compression of the arteries at the ring. Reduction of a hernia by the taxis in the first stage of strangulation is always practicable, though not always easy, and sometimes impossible, if conducted on the principles generally laid down. If the surgeon, supposing he must first return the portion of intestine immediately engaged in the ring, pushes and pulls, or kneads the tumour by a successive motion of the finger and thumb, he will seldom succeed in a tight case, even in this stage. And further, if he be intent only on "getting the contents of the intestine out," he will be apt to relinquish his efforts in disappointment after a short trial.

There is something to be done before either of these are attempted. The tumour is full of distended veins, the blood of which must first be returned very gently and patiently; not by pushing and kneading, and thumbing, but by gentle equable compression on all sides of the tumour, the abdominal and psoas muscles being previously relaxed. Now, it is evident that the venous blood, returning in obedience to the pressure of the surgeon's hands, through a very small aperture, *must needs return slowly*. If the tumour contain half a pint of blood, which is returned at the somewhat rapid rate of a drachm per minute, it will take sixty-four minutes to return the whole. Here, then, is a full hour's work to be done, and in the case of a very large hernia, it has been known to occupy two hours and twenty minutes, and two pair of hands, to accomplish this first step in the reduction! What, then, do surgeons mean by trying the taxis for a quarter of an hour, or *not at all*, operating on *the moment*, when they have the safe work of an hour or more before them? So soon as the venous blood is returned in any quantity, the sensible diminution of the tumour shews the practitioner that his work is done. It is as well to keep up the pressure to the end, but the peristaltic action will soon do the rest; the gas in the tumour rushes through the now more roomy ring, with the well-known gurgling noise; the solid contents next; and, lastly, the fatty portion, (omentum, &c.,) follow the returning bowel through the ring.

In the next stage, (that of inflammation,) the same practice carried out with yet more tenderness and patience, will generally accomplish the same result. In the third stage, (*sphacelus*,) the operation may be necessary, but will rarely be successful. The symptoms of inflammation and sphacelus are sometimes obscured, and it is not my object to lay down any rule in these extreme cases, for or against the operation, but only to suggest a more eligible and successful mode of employing the taxis,—a mode which, after twenty-seven years trial, I have never known to fail; although I am by no means prepared to say it never will fail, or that the operation with the knife is never necessary.

Your correspondent will perceive that I differ from him in theory only by a shade, and that our practice is essentially the same. I see no objection (except where approaching sphacelus is to be apprehended,) to the application of cold, in conjunction with gentle, continued, persevering pressure; but I should prefer a previous trial of pressure, as an expedient often necessary on his own shewing, and in my experience always successful. Let no one, however, to whom these views may be new, run away with the notion that the reduction of a hernia, long strangulated, is supposed to be an easy or simple operation. Any man with a steady hand, who is familiar with the anatomy of hernia, can open the sac and divide the tendon. This is easily enough accomplished,—it is but *cutting* the Gordian knot; and yet, strange to say, a man who does this, often gets more credit, even with his brethren, than he who, superior in skill, can *untie* it! The *operator*, as he is called, is handsomely paid, but all the reward obtained by the man who reduces a hernia without risking his patient's life, is, perhaps, the transient gratitude of the sufferer, and a week's lumbago.

I am, Sir,

Yours respectfully,

THOMAS HUNT.

Herne Bay, December 18, 1847.

CASE OF AMPUTATION PERFORMED UNDER THE INFLUENCE OF CHLOROFORM.

By T. Berry Torr, Esq., Surgeon, Barnstaple.

On Thursday afternoon last, (January 9th,) I was requested by my friend Mr. Clarke, of Lynton, to meet him on the following morning, in consultation on the case of a very old man, 87 years of age, named Thomas Bale, residing at a lone cottage at the higher part of the parish of Brendon, twenty-five miles from this town, who had sustained a most severe compound fracture of the left leg, produced by one of those huge blocks of stone, (so common in that locality,) weighing about a quarter of a ton, having rolled down on him from a steep declivity, and crushing his leg between it and another stone of considerable size.

On reaching the patient, in company with Mr. Clarke, on Friday, an examination of the injury too sadly proved that the account of it which had been given me

was by no means overdrawn. I found a most extensive laceration of the soft parts on the inner side of the leg, upwards of eight inches in length, through which the denuded fragments of bone were protruding in every direction; and on the outer side of the leg was a similar laceration six inches in length, attended with the same comminuted state of the bones. In this state of things it became our duty to point out to the patient and his friends, that not even the most remote chance of prolonging his life existed, save by recourse to amputation, which was willingly acceded to. Accordingly, having previously provided myself with a supply of genuine chloroform from London, we at once proceeded to administer it to him, on a plan which I somewhat modified from that used by Professor Simpson.

The desired, and it may fairly be said, truly astonishing effect, was produced in a little more than seven minutes; the patient after a slight twitching of the muscles, passing off into an apparently profound sleep. In this state we carried him from his bed, and placed him on a previously-prepared table in the adjoining room, without his evincing the slightest evidence of the pain, which under other circumstances he must unavoidably have suffered. The necessary preliminaries having been carefully adjusted, and the chloroform again applied for a few minutes, in order to ensure its full effect, I immediately proceeded with the amputation, which was performed in rather less than three minutes, Mr. Clarke, who rendered me very efficient assistance, and myself, being as much delighted as were the family astonished, at observing that at no step of the operation did our now unconcious patient shew any symptom whatever of enduring pain.

Shortly after we had replaced him as comfortably as possible in bed, he commenced being very talkative, would not believe his leg had been removed, and when questioned as to whether he had not felt pain, he replied, No, he had not felt any pain; he thought he had been asleep! He soon after this sang several snatches of a favorite old song!! And then passed into a most tranquil sleep, in which state we left him.

Remarks.—From the ossified and diseased state of the arterial trunks met with in the stump, added to the patient's great age, the chances of recovering are of course sadly against him. Amputation below the knee was, however, the only plan of treatment which the *extensive* and *severe* nature of the injury would possibly admit of; and the desired anæsthetic effect of the new agent was certainly *most successful* and *complete*. One circumstance, however, which particularly arrested my attention during the process of securing the vessels, was the highly venous appearance of the blood issuing from the arteries which I particularly pointed out to Mr. Clarke; and I further remarked, that in proportion as the special effect of the chloroform passed off from the patient, the blood from the small muscular branches resumed its arterial character. The *modus operandi* of this truly astonishing, and (as far as the interests of humanity are concerned) certainly invaluable agent, has not, that I am aware of, been as yet fully explained, but if the foregoing remarks are confirmed by further observation, they would, I think, lead to the inference that its effects are produced through the medium of a highly and perhaps peculiarly carbonized condition of the blood, acting on the sensorium and nervous system; and it will, therefore, be the province of further observation and experience to determine whether any and what degree of injurious influence may thereby be produced on the system, as to its restorative action so much in general required after the major operations of surgery; and whether such effects are calculated to overbalance the high *desideratum* of, as it were, annihilating human pain and agony on such occasions.

TWO CASES OF DELIVERY UNDER THE INFLUENCE OF CHLOROFORM.

By Herbert W. Budd, Esq., Surgeon to the City Gaol, Worcester.

Case 1.—January 23, 1848, I visited Mrs. Price, aged 27, in labour with her third child, at a quarter before five, a.m. Her pains commenced at eight o'clock the preceding evening, were very frequent and wearing, about every three minutes, and had been thus nearly the whole night; pulse 80; os uteri dilated to the size of a crown-piece; the head of the child had entered the cavity of the pelvis; complexion florid; of spare person. Three days ago she had a severe fall on the back, and since that time has had a constant cold weight in the bowels, and has not felt the child. Complains much of her back. On my naming the advantages of chloroform, she entreated me to use it.

Half-past five, a.m. I administered fifteen minims by means of a sponge. In less than a minute she seemed to be comfortably asleep, though easily roused. She had several pains, with intervals of three or four minutes, without feeling them; afterwards she had several in the natural state, which she said were much deadened. The parts became more relaxed, the uterine action not at all diminished in power or frequency. In the intervals she seemed to be asleep.

¼ to 6 o'clock 15 minims, with the same results.
¼ past 6 „ 15 „ „
¼ to 7 „ 15 „ „

Seven o'clock, 30 minims. The membranes gave way under a very strong expulsive effort, and a large quantity of liquor amnii escaped. The head immediately pressed on the perineum. Quite unconscious.

10 minutes past 7. 30 minims.

20 minutes past 7. The child was born, and from its appearance had been dead some days; much swelled. In from five to ten minutes the placenta came away with facility, and the uterus contracted firmly. She became conscious a few minutes after the birth of the child, and assured me she was quite ignorant of its having been born. She said, "I have been in another world." She felt no pain on the expulsion of the placenta, although quite sensible. I think it right to add, that the passage of the shoulders was very tedious, and I was obliged to give considerable assistance in their delivery, although the throes of labour were very strong.

She has gone on favourably in every respect since. I saw her to-day, January 31st, and she is quite comfortable.

Case 2.—Thursday, January 27th, I was sent for to Mrs. Lockley, in labour with her first child. I saw her at a quarter to four, p.m. Pains had commenced at eight the preceding evening, with an interval of half an hour for the first few hours; they then became more frequent, and for some hours previously to my arrival came on every five minutes. Expulsive pains weak; os uteri dilated to a size larger than a crown-piece; great thickness of perineum, and a considerable portion of the anterior lip of the uterus to be obliterated. My impression was, that she would not be delivered till twelve that night. On naming the chloroform, she was anxious to have it administered. I did so with the most satisfactory results, as the particulars subjoined will, I think, amply testify.

Mrs. Lockley is of a florid healthy appearance, rather stout, aged 25. Pulse 110. On examination the vagina evinced great irritability.

Quarter past 4, p.m. Fifteen minims of the chloroform were administered with a sponge; she was under its influence in less than a minute. In three minutes uterine action came on of a more expulsive character than before; the parts were strikingly relaxed; irritability of vagina vanished. After an interval of four minutes another pain came on. She afterwards opened her eyes, and on being asked whether she felt any pain, said "No! But I was conscious of something." She dozed between the pains. She then had six pains in the natural way during the next half hour; they were strong, not at all diminished in power or frequency. She assured me they were much deadened.

Ten minutes to five, 20 minims. In two minutes a very strong pain came on, followed by another in a minute, under the influence of which the membranes gave way. She seemed comfortably asleep at this time.

Five minutes to five. During a strong throe of labour, I pressed firmly on the perineum internally; she seemed however quite unconscious.

Five o'clock. Quite recovered from the effects of the chloroform. For thirteen minutes from this period she had four pains, not at all diminished in power, &c. Sensation of pain much diminished.

13 minutes past 5 ..	20	minims,	with like effects.
½ past 5	30	..	..
6 o'clock	30	..	..
25 minutes past 6	30	..	..
20 minutes to 7	30	..	..
5 minutes to 7	30	..	..

Three minutes after seven, 60 minims; pains are now very forcing; head begins to press on the perineum. Sixty minims.

20 minutes after 7..	30	..	..
½ past 7.....	30	..	..
25 minutes to 8	30	..	..
12 minutes to 8	30	..	..
5 minutes to 8	30	..	..

For the last half-hour or more has been in a dreamy unconscious state.

Eight o'clock. The child born alive, a fine girl; the placenta followed in about five minutes; uterus well contracted; no hæmorrhage.

Shortly after her delivery she became conscious, but seemed much disposed to doze. She was conscious of the placenta coming away, but did not feel any pain; she screamed out at the last throe but one preceding the passage of the head. On my naming this to her, and fearing that she must have suffered much at the birth of her child, she replied, "Oh! no sir, I knew nothing about it; I was in a dream, and I saw my brother drowning; I called out and tried to catch hold of him, to prevent him from sinking."

Friday, 10 a.m. I was informed that she slept for four hours after I left her last night. She had a good night, and has gone on favourably ever since. The lochia were natural; the milk appeared on Saturday night.

February 1st. I found her sitting up in bed, with the child in her lap, and looking well.

CASES FROM PRIVATE PRACTICE.*

By John Richard Wardell, M.D., Edin.;

Late President of the Royal Physical and Hunterian Medical Societies, Assistant Pathologist in the Royal Infirmary, Edinburgh, &c. &c.

INFANTICIDE.

Remarks.—When employed at the inquest held on the first of these cases, it was not without a full consciousness of the serious duty which was then to be discharged;—serious, because there was no circumstantial evidence beyond the mere fact of the discovery of the body, to lead to the supposition that the child had been murdered, and upon the *ipse dixit* of the medical evidence, would the nature of the verdict, mainly, if not entirely, be decided, and therefore upon the view about to be taken of the matter, would be based important dependencies, it might be, the life or death of another individual. It is not at once sweepingly to be concluded that because the body of a child is found, as in this case, under suspicious circumstances, it has been feloniously destroyed; the mere discovery of the corpse, although it might highly favour the presumption, could not alone warrant us in arriving at such an inference; other enquiries would have to be made, and certain questions previously decided,—for instance, as to whether the child were at maturity; if it had maintained a separate existence; if its death had resulted from wilful or natural causes; what were the proofs of its having been maliciously destroyed, with like questions, which ought of course to be determined.

In former times concealment of pregnancy or of birth in this country were held capital offences, and many unjustly suffered under this barbarous law; in later

* Continued from page 40.

times, however, this and similar cruel statutes have wisely been repealed, and now none suffer where it has not been satisfactorily proved that murder has been really committed. The law, with a proper humanity, supposes all children to be born dead, the *onus probandi* therefore being thrown upon the prosecution, and not as before upon the accused. When a female belonging to a respectable sphere of life is heartlessly betrayed, and finds herself in a condition which, as soon as known, must inevitably hurl her from her status in society, if such do not bring her to utter ruin; when she droops under the withering consciousness of self-debasement, consequent upon the loss of virtue, and knows not how or where to seek for refuge, or look for sympathy; week after week passes on in this dreadful state of irresolution and disquietude of mind; she dreads to reveal the "big secret of her breast," which must be fatal to her respectability, and the certain destroyer of her peace; perhaps by successful artifice she adroitly manages to hide her shame until very near, or even to the end of pregnancy; the mind has been long lacerated by its torturing reflections, the health has suffered, the spirits are depressed; labour with unexpected suddenness supervenes; in the agonies of mental and corporeal suffering, her anguish is so intense as for sometime to deprive her of consciousness; the child is lost during the process of unaided delivery, or for the want of proper assistance dies after it has been expelled, and for a moment maintained an independent existence. Might she not on calm, deliberate reflection, after having regained her senses, and finding her offspring dead, dispose of the body with little or no compunction of conscience, by which decision she might hope this deviation from the paths of virtue would be veiled from the public eye,—reputation and standing preserved,—the feelings of friends be spared,—the future, instead of presenting a saddening scene of misery, would thus, under repentance for past folly, hold out cheering hopes of future happiness. She conceals it; the body chances to be found; the mother is made out, she is accused, and though innocent, few or none suppose so; she is arraigned for one of the darkest of crimes.* Instances of this kind have occurred. Again, temporary derangement has been known to come on about the time of delivery. From such and other circumstances, might not the mother destroy the new being at a time when she was irresponsible for her actions? Certainly. The child might be suddenly born when the woman was at stool, faintness and insensibility come on, and the infant suffers. To cite a case in point which happened a few months ago, the detail of the autopsy of which is given before. Mr. Ness, the coroner of the district, in a letter, thus speaks of the instance:— "The verdict of the jury was that the child died from suffocation, but by what means produced there was no evidence. The mother's story was that the child was born while she was attempting to have a motion, but she fell on the floor insensible, and when she came to her senses the child was laid on the floor, dead. She acknowledged placing it in the well a few hours after." The woman was acquitted of the grave crime of infanticide, by receiving the advantage of the possibility of the infant having so suffered, but she was punished by a sentence of two years' imprisonment, for concealment of birth. From the determination of blood which there is induced, by the violent expulsive efforts in the encephalon, as also from the great irritative disturbance which the process of parturition is apt to produce in the cerebro-spinal system, temporary insanity might thus, as it does sometimes, occur. The writer knows of a person who has borne several children, in whom, towards the end of two or three of her pregnancies, mania became manifest, which however vanished soon after delivery.

It is clear, then, that it would be exceedingly wrong to say, that because the body of an infant was under suspicious circumstances discovered, its life had been wilfully taken, and as above observed, certain incontestable facts would in addition be indispensably requisite before we could conscientiously depose a statement so important. On a perusal of several authors on infanticide, it is surprising to see the indefiniteness of their statements, and that there appear to be exceptions to every rule associated with the subject; such indeed, are "these glorious uncertainties in the law," that it is quite obvious an ingenious and well-read pleader might get off parties with whom there was no moral doubt of guilt, nor could they be punished unless confession were made, or there were actual witnesses of the deed. The medical evidence is summoned to give his medical opinion as deducible from what is seen sub oculis, and there his duties terminate; his depositions are to be made irrespective of prejudice, and it then remains with the jury to decide as to the nature of the verdict. The medico-legalist ought in all cases to base his inferences upon a general review of *all* the facts, and not upon an isolated consideration, or he may incur the risk of erroneous deduction.

In these observations it will briefly be endeavoured to shew that in the above reports there are some striking resemblances, and by drawing a comparison between the two, it will be seen they are in many respects alike. Dr. Wright's case appears to have been taken with much anatomical exactness, and that gentleman has very properly noticed all those leading features, which the case and circumstances seemed to demand.

Respecting the body of the female, from its general aspect the most cursory observations rendered it manifest that but little time had elapsed since its birth, there being no indications of decomposition, nor indeed anything much dissimilar to what is perceived

* See Dr. Hunter's Eloquent Tract.

shortly after death. From the particulars which are given, it must needs be deemed incontestably clear, that both were at maturity, nor are there any feasible grounds for the supposition that they could not have supported a separate existence. Their lengths, the abundance of hair, their weights, the well-formed nails, &c., exemplified that they had not been born long, if at all, before the full period of gestation. The length of the body of a matured infant at birth, has on an average been stated at eighteen inches. One of these we see measured nineteen inches and three quarters, and the other twenty inches, which was thus about a tenth more than ordinary. The hair and nails do not become perfectly developed until the last month of utero-gestation, but in each they reached beyond the tips of the fingers. Some have asserted that at the ninth month the umbilicus will be found inserted at the point corresponding with the exact centre of the body, which was the statement of Chaussier; but M. Moreau has more recently demonstrated this to be incorrect, for sometimes the insertion is an inch or an inch and a half nearer the pubis. The saponaceous matter which is usually noticed at birth, and that by certain writers is deemed indicative of maturity, was abundantly present in the female, but on the male none was to be observed, which suggests the question,—had it been washed before, or subsequent to death? "At the ninth month the sebaceous secretion is copiously found on the skin," says Dr. Cummin, when alluding to this point. When children are still-born, the thorax, owing to the yet collapsed condition of the lungs, and the influence of external atmospheric pressure, has not that full and rounded appearance presented when respiration has been thoroughly performed. When free breathing has taken place, the intercostal spaces are completely obliterated, and the surface feels even to the touch. In the former illustration the plumpness of the chest rendered it highly presumptive, before any dissection had been made, that the lungs on being exposed would be found to have attained their normal magnitude of expansion, and this undoubtedly by the respiratory function having been properly in action.

On giving evidence at the examination on the inquest, I specially directed the attention of the jurors to the state of the funis, which was soft, shining, flexible, and pearly-looking; at its umbilical insertion there was not the least appearance of decay; of itself there was no wrinkled contraction, its colour was unaltered, and indeed in all its characteristics it was little, if at all, dissimilar to what it is at birth. The extent of the cord that remained was not less than three times the length that is left when it is divided in the usual manner by a midwife; and two additional points of considerable importance were indisputably evident:—first, that it had been torn in two; secondly, there were no traces of any ligature having been applied. In Dr. Wright's case the cord had also been torn, and the extremity was ragged, nor were there indications of a ligature. Being thus rudely rent asunder, and no string having been tied around, attested that the ordinary precautions had not been observed in order to guard against the supervention of hæmorrhage—(that is, supposing the children to have been born alive, of which there was no doubt whatever,)—a consideration which from custom alone is in common cases never omitted by those in attendance, and nurses and women-attendants are ever very solicitous respecting the tying of the navel-string, and always ascribe to this duty more importance than is really of consequence. Any woman in attendance, where the ordinary care and preservation of the child were considered, would never think of forcibly breaking the cord; and in those instances where the child is precipitately expelled, when the mother is in an erect position, the laceration, as confirmed by experiment, by far most frequently takes place at one or other of its insertions, generally at the umbilical end;* and supposing it to have been still-born, if no criminal intentions had been entertained by the mother, or party or parties present, it is fair to presume that some cutting instrument would have been employed. It is true, granting the presumption of still-birth, that they might be careless of the manner in which it was severed, yet such does not do away with the very high probability of the less grave offence—concealment of birth—but rather confirms the supposition. The manner in which the cord had been divided in No. V., added to the suspicion of its being feloniously destroyed; and in No. VI., by its being lacerated towards the umbilical extremity, we are led in this particular to give the accused the benefit of the probability that it had been broken during precipitate expulsion. When the cord is kept insecure, the infant may die from the loss of blood, which is termed *infanticide by omission*; yet if the circulation has undergone its proper change, but few (if the ligature were not applied,) would die from hæmorrhage; nevertheless, such is the law of the country, and where it can be indubitably proved that such precaution is willingly and maliciously omitted, the accused becomes liable to the penalty of the crime. When a child has thus suffered, the body looks white and bloodless, the large vessels are found drained of their contents, and little attention is required to correctly decide upon the cause of death.

In neither of these examples was there any evidence of the kind; in the female the viscera were normally supplied with blood, and from Dr. Wright's report the same remarks are equally applicable relative to the male infant.

In both instances it is mentioned that they were smeared with meconium. The escape of this matter has been deemed confirmative of the supposition that independent life had been carried on;—in other words,

* Klein.

that the child had been born alive. This is merely mentioned amongst other facts, yet it is, perhaps, not much to be relied upon, because in breech cases, where the infant is still-born, the posterior parts are often covered with meconiumnal matter.

The lineal mark on the anterior part of the neck of No. V., from the excoriation, the distinct ecchymosis and the bruise-like patch spoken of above the clavicle, rendered it highly presumptive that such had not resulted from the wrapping round of the funis, nor yet from the only manner besides in which it could naturally have been done during parturition, viz., by the firm embrace of the edges of the os uteri after the head had passed out of the womb. Now, if it had been contended that the umbilical cord had strangled it, respiration would not then, of course, have taken place, the lungs would have been uninflated, and thus the functions so necessary and indispensably requisite to life, would have been prevented from ever having commenced, instead of having begun and been then suspended; but here the pulmonary organs gave undoubted evidence of respiration having been fully and perfectly carried on. But for the sake of argument we will suppose that the child was born alive, and that after its expulsion, the cord from the altered position of the mother, or the movement of the child, became tighter, and thus prevented the ingress and egress of air, the lungs would not then by such imperfect respiration have been so entirely dilated, because the state of expansion in which they were found, unavoidably pre-supposed these organs having for a shorter or longer duration performed their functions normally. If it had been strangled by the cord the marks left would have been far less distinct, and very different from those ensuing from violence. The eminent German writer Klein, thus expresses himself on this point:—"I have never met," says he, " with an instance of marks of injury of the kind supposed, ecchymoses or sugillations, produced by the orifice of the uterus, or the umbilical cord, although I have known a great number of cases in which the neck of the infant had been strongly girded by the funis once or twice twisted round it, strangulation having thus been actually produced or rendered most palpably imminent." The glairy lubrication of the cord would prevent such friction as would be required to abrade the cuticle; and besides, if the stripe had been produced in this manner it must needs have been broader and less clearly defined. On carefully dissecting down to the subcutaneous cellular tissue corresponding both with the line and bruise, extravasated blood, as mentioned, was at once apparent, and the substance of the sterno-cleido-mastoideus muscle showed that rupture and effusion of the minute vessels proper to its texture had ensued, which it is exceedingly probable had taken place during life. It is true, that, according to the statements of certain experimental writers, an ecchymosis *may* possibly be produced after death (properly so called,) has taken place, owing to the capillaries retaining in some degree their action after the heart has ceased to beat; at least, such are the affirmations of Le Gallois, Wilson Philip, and other philosophical investigators.

It is said that capillary action is the last of all the corporeal functions, in ceasing their operations after the more manifest evidences of life, strictly so termed, are permanently suspended—the fibrillæ of nerves it thus appearing conveying the stimulus to vascular action, though in an impaired and imperfect manner, subsequent to the central organs having terminated their functions. Granting such doctrine to be to some extent true, we may, as said, conclude that the functions of the capillaries would then be but imperfectly performed—that their contents would pass along their course more tardily from the non-aeration of the blood and its consequent inspissation; hence it would not be so readily effused and an ecchymosis thus produced would be far less perfectly formed than during life, and therefore to ascribe the distinct, well-marked, and unequivocal extravasation in this instance, to injury after death, would be highly improbable.

It is undeniable that the accused has a right to the advantage of the most distant chances, and the common spirit of humanity alone would always dictate every leniency towards any one arraigned for so dire an offence; yet there is a converse duty indispensable for the maintainance of justice and the security of society, which renders it proper, and is imposed on all conscious individuals concerned in these investigations, that any far off possibility should not be made the loop-hole for the escape of crime, and the bearer away of guilt beyond the pale of the law. In evidence, it was given as an opinion, that these marks had been caused during life. "When the mark is deep," observes Mr. Taylor, " and much ecchymosed, with extravasating blood beneath, and ruffling and laceration of the skin, it is impossible to attribute this to the umbilical cord."* Orfila, respecting the signs of strangulation, delivers himself as follows:—"1. That a circular mark round the neck, with a corresponding effusion into the subjacent cellular tissue, indicates strangulation during life. 2. That though it be impossible to deny that this mark was produced by the orifice of the uterus or the umbilical cord, yet, since no well-authenticated case warrants us in admitting it, it is a natural supposition that the mark in question is the result of criminal violence. 3. That if this mark be combined with appearances denoting that respiration had been previously completely established, our inferences must be so much the stronger; for stricture by the neck of the uterus, or by the funis, cannot be supposed to have proved fatal with such appearances.

* Taylor's " Medical Jurisprudence," page 488.

4. That dark spots on the neck, without corresponding subcutaneous effusion, do not warrant the conclusion that the infant was strangled; but,—5. That, on the other hand, neither does the absence of such spots or such effusion, or of both together, strictly authorize us to conclude that strangulation did not take place."*

The correctness of the latter opinions of this very eminent medical jurist is quite incontrovertible, and they well accord with the conclusions which must be deduced from the facts supplied by the case in question. Referring to the above report of the *post-mortem* examination, the reader will perceive that behind the pharynx, between the soft parts and the cervical portion of the vertebral column, some dark coagulated blood was discovered, and that the brain was in a highly congested condition, rendering it still more manifest that strangulation had been the cause of death. On removing the calvarium, the dark fluid blood that oozed away was very considerable, and manifestly showed that there had been very great determination of the vital fluid to this part, and which had been owing to vascular obstruction. In Dr. Wright's case the encephalic mass, and the vessels proper to its coverings, had been preternaturally distended, yet, judging from his report, the congestion had not been so great as in the instance examined by myself.

Hospital Reports.

NEWCASTLE-ON-TYNE INFIRMARY.

CASES IN SURGERY ADMITTED UNDER THE CARE OF J. M. GREENHOW, ESQ., SENIOR SURGEON TO THE INFIRMARY.

Reported by Mr. S. Miller, House Pupil.

FRACTURED SKULL.

The following cases are not without interest, as illustrating the less degree of danger resulting from such accidents in the young than in adult patients, in consequence probably of the more yielding and elastic character of the skull in the earlier periods of life.

Case I.

William Murray, aged 2 years, a stout healthy-looking child, was admitted November 6th, 1847, at 9 a.m. Half an hour previous to his admission he had fallen from a first-floor window, striking his forehead on the stone pavement below. There was a small wound of the scalp over the middle of the os frontis accompanied with fracture of that bone; the left margin of the fracture was depressed completely below the level of the right margin, so that a probe could be passed beneath the latter. The boy was quite sensible when first brought to the Infirmary, and his breathing was natural; pulse quick, and very weak. In about half an hour after his admission his breathing became stertorous, and there was occasional vomiting.

At ten o'clock Mr. Greenhow arrived, and with a scalpel enlarged the wound, so as to display the extent of the fracture. A small portion of bone was removed with Hey's saw; the depressed bone was then by means of an elevator easily raised to its natural position. The edges of the wound were brought together by a single suture, and adhesive plaster. Orders were given to the nurse to keep cold cloths constantly to the head. Very little blood was lost during the operation, nevertheless, the child was very much depressed, the pulse remaining exceedingly weak, and the insensibility continuing.

To take two grains of calomel every three hours, until the bowels are freely moved. To have weak brandy-and-water occasionally, in small quantities.

10 p.m. He has now become quite sensible, and knew his mother quite well this afternoon. Pulse firmer, but still quick; bowels have not yet acted. The colour has quite returned to the face; he does not notice any one unless he is roused. Continue the calomel, and take a tea-spoonful of castor oil in the morning.

7th. Has passed a very quiet night; speaks when roused; bowels have acted freely, and he has passed his urine; pulse quick. Some swelling and redness of forehead has taken place, so that the eyes cannot be opened. Repeat the calomel at bed-time.

8th. Is quite sensible; bowels act regularly; pulse quick; swelling of forehead increased about the right eye. Repeat the calomel at bed-time.

9th. No bad symptoms. On going to the ward this morning he was sitting up playing with his sister, apparently quite well. Swelling of forehead nearly gone, but a slight abscess has formed in the left lower eyelid, which was opened. The wound is healing favourably. Repeat the calomel, if necessary.

He continued to go on very well until November 3rd, on which day he left the hospital, quite well in health, and the wound as nearly healed as possible.

Case II.

Wm. Edward Innis, aged 8, a spare and delicate looking lad, admitted Nov. 4th, 1847, at four, p.m.

A few minutes before admission, he had fallen from the top of a high wall, alighting on his head. There was a large jagged wound, two inches in length, above the outer angle of the left orbit; on examining the wound with the finger, the bone was found to be extensively fractured, a piece upwards of an inch square being entirely separated from the surrounding bone, and considerably depressed below its level. The bone was so broken that the inner table was more extensively injured than the outer, the edge of the latter projecting somewhat over the depressed portion of bone. The child was perfectly insensible; his breathing stertorous; pupils contracted, but obedient to light; face pale, and surface of body cold; pulse quick and weak. Mr. Greenhow arrived shortly after his admission, and proceeded to raise the depressed bone; this could not be effected without the use of the trephine; by the application of which, a little above the fracture, an

opening was made for the introduction of the elevator, by the means of which and a pair of forceps, the depressed bone was raised to its natural level. During the operation there was much convulsive struggling, affecting chiefly the left side, the right side on the contrary being paralyzed. After the operation the pulse became fuller and more rapid, and the insensibility continued. Very little blood was lost during the operation. A suture and adhesive plaster were applied to bring the edges of the wound together, and cold lint ordered to be kept constantly to the head.

To take four grains of calomel every four hours, until the bowels are freely opened.

10 p.m. Bowels not yet open; pulse quick and weak; patient still insensible. Repeat the powder every four hours.

9th. Bowels have been freely moved; pulse stronger; pupils act well; skin hot; not sensible. Repeat the calomel at bed-time. Apply mustard poultices to the feet.

10th. Is still insensible; bowels act regularly; makes water well; face red and hot; pulse quick. Some twitchings of the left, but cannot use the right extremities, he does, however, occasionally move them. Repeat the calomel at bed-time, if necessary.

11th. Wound looks well, but no union by the first intention has taken place. Seems to be sensible to-day. Bowels act regularly; pulse firmer and slower. Wound was dressed with a little chalk ointment.

He continued to improve gradually until the 30th of November, when he left the infirmary, the wound healing well, since which he has not returned, but I have heard that he is quite well.

January 4th, 1848. I met him whilst walking out; the face is slightly drawn to the left side, but he is in the enjoyment of perfect health; small portions of bone have been discharged from the wound, which is nearly but not quite healed.

Case III.

STRICTURE OF THE ŒSOPHAGUS FROM SWALLOWING SULPHURIC ACID.

John Lyans, aged 24, labourer, from Stockton-on-Tees, in Durham, admitted into the Newcastle Infirmary, September 20th, 1847; a healthy-looking man, but very thin from recent loss of condition. Ten weeks ago he swallowed by mistake a quantity of sulphuric acid; a few days afterwards some sloughs in the throat separated, and the ulceration healed, but he experienced a gradually increasing difficulty in swallowing, so that, on admission, he could take liquids only in small quantities. He had been under the care of a medical gentleman before admission, but no mechanical means had been used for dilating the contracted œsophagus. The pulse was weak; bowels regular. A small elastic *urethra* bougie was with slight difficulty passed through the contracted œsophagus. To have liquid diet.

23rd. Bougie passes more easily. From after this time the bougie was gradually increased in size until the 13th of October, when a very large rectum bougie could be easily passed; his appetite was now good; he could swallow without difficulty; had gained flesh, and in fact had recovered his ordinary health when he left the hospital.

The preceding case is remarkable both from the cause and the degree of the contraction of the œsophagus, which was so considerable as nearly to prevent the admission even of liquid nourishment into the stomach; nor was the facility with which it yielded to mechanical treatment, carefully applied, less remarkable. The action of the escharotic must have been confined to a very limited portion of the œsophagus.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, FEBRUARY 9, 1848.

The attention of the public press, has been of late, drawn very strongly to the mode in which the duties of Union Medical Officers are discharged, and much virtuous indignation has been expressed at certain instances of supposed neglect which have occurred. One of these has been made the subject of an inquest, and the verdict of the jury has cast most undeserved blame on the conduct of the medical officer in attendance. We allude, of course, to the case of Dr. Berncastle, who, as assistant to Mr. Bottomley, of Croydon, attended a pauper, on being summoned by the friends, in a case of midwifery, paid some three or four visits, and devoted several hours of valuable time, while the parties were hunting up the relieving officer, and referred from that authority to the Board of Guardians, for an order. The order was ultimately refused. Dr. Berncastle was forbidden to attend on the part of the parish authorities; he, consequently, withdrew his attendance, having, however, transferred the case to another practitioner. The case turns out unfortunately; the patient sinks, it is said, from exhaustion; an inquest is held, and Dr. Berncastle is by the verdict pointed out for public reprobation. Why? Because he humanely gave his time and services until the parish authorities could make up their minds to grant the medical assistance required?—or when they refused that assistance, for withdrawing from the case, as their officer, and leaving it in the hands of another practitioner?

The unfortunate sufferer was, however, either a pauper or not. If she was a pauper the order should have been forthcoming; if not, what had the guardians to do further with the matter; yet we find them assembling together,

discharging Dr. Berncastle, and censuring Mr. Bottomley, their own officer, because Dr. Berncastle, over whom they had no control, had ceased attendance upon a case in which they had declared they had no concern! But we hold that by this act they have admitted that the case was under their own jurisdiction,—that it was not the case of a private patient, but of a pauper, and by refusing the order in the first instance, they must have intended to betray their medical officer into a gratuitous attendance on a pauper case, and on his failing to do so, they are themselves solely responsible, not only for the injustice done to him, but for the whole of the mischief which resulted.

To return to the inquest: we are of opinion that the Coroner's Court properly conducted is a most important aid to public justice, and that the Coroner's inquest affords a wholesome check on the perpetration of crime and abuses of various descriptions. No Coroner ought, however, to sanction an intermeddling spirit; and if juries expect their verdicts to carry due weight with them, very careful should they be in the imputation of blame upon parties not concerned.

The question before the jury in this instance was the cause of death; but why should they have stepped out of their way to implicate Dr. Berncastle in it? Are medical practitioners, whose time is their estate, and the use of it their means of subsistence, to devote that to an unlimited extent at the call of, or under penalty of censure by, any public body, without fitting remuneration being assigned to them. If the case was a pauper one, the relieving officer, and the Board of Guardians, were the parties who should have been censured;—if not, why is Dr. Berncastle's humanity to be called in question, because having already given much, he did not give more? We are informed that the patient sank from exhaustion:—suppose these said twelve jurymen,—bakers, spirit dealers, &c.,—to have been severally informed of this, and roused at midnight for the supply of the necessary food and stimulus, and their wives called upon to come out and administer them on the plea that the woman had no nurse, nor the means of procuring one; would any one of them have bestowed as much attention on the request as Dr. Bernecastle did to the call upon him? Would they not have said,—No, the public provides for these things! go to the relieving officer! and then have closed their doors against the applicant, with a feeling perhaps, of personal injury, that such an application should have been made.

Now we should scarcely have deemed the conduct of such prejudiced and misjudging people worthy of comment, had it not been that we find some of the public journals joining in the cry, lending their aid to hunt down an oppressed man, and taking occasion also to cast most undeserved obloquy on a highly meritorious body of men. The following is the professed opinion of one of the most enlightened of these journals, whose usual acumen and straightforward dealing seem to have been sadly at fault in this matter:—

"It would seem that there is something peculiar to the position of a parochial surgeon, that renders him liable to a strange distortion of views on the subject of common humanity. In most of the cases of neglect that have shocked the public for the last few years in consequence of the mal-administration of the laws relating to the poor, it has been a remarkable fact that the medical officers concerned have apparently believed that there was nothing in their conduct to warrant the disgust it has elicited. This strange insensibility among a certain class of practitioners has enabled the parochial guardians to find candidates for offices that must have remained vacant if the entire medical profession had taken a proper view of its duties and its position. Such, however, has not been the case, and it has accordingly happened in numerous instances that a set of unfeeling directors or guardians of the poor have got hold of a medical man as heartless as themselves, and, by keeping each other in countenance, they have all been emboldened to the commission of acts of the most hardened cruelty. Their unconsciousness of having deserved the odium incurred is one of the most lamentable characteristics of the sort of offenders to whom we allude, for, as no fault can be avoided until it is seen, their blind obtuseness almost precludes all hope of amendment."

We quote this statement to shew the Union Medical Officers to what they are exposed, and the necessity which there exists for active exertions in making use of every effort to obtain for themselves their just right to an equitable payment for their services. We cannot go further into this case here, but before concluding we would take the opportunity of expressing the pleasure we have received in the perusal of the excellent leading article in the *Lancet* of January 29th, on the case of Dr. Berncastle, in which the whole subject is most ably discussed.

We have observed in the Norwich papers the subjoined honourable testimonials to the long-continued and valuable public services rendered by Mr. Page Nicol Scott, in the capacity of Surgeon to the Norfolk County Gaol. On the

occasion of Mr. Scott's retiring from this office, in consequence of ill health, after thirty-three years faithful discharge of its duties, the chairman of the Quarter Sessions writes to him as follows:—

"Shirehall, 7th January, 1848.

"SIR,—As Chairman of the Court of Quarter Sessions, I have been instructed, by an unanimous vote of the Justices assembled, to express their sense of the value of your long and faithful discharge of the duties of Surgeon of the County Gaol, and their regret, that the state of your health makes it necessary for you to resign the office.

"I remain, Sir,

"Your most obedient servant,

"HENRY DOVER, Chairman.

"P. N. Scott, Esq."

The following letter from the Government Inspector of Prisons was read in the Court, when Mr. Scott's retirement was announced:—

"Kensington, 16th December, 1847.

"SIR,—I have to acknowledge the receipt of your letter of the 4th instant, announcing to me your intention of retiring from the office of Surgeon to the County Gaol, at Norwich, and requesting me to bear testimony to the faithful execution of the duties entrusted to you.

"It is, I assure you, a very agreeable task to perform, although mingled with regret that the cause of your retirement from public life is serious illness, and generally declining health. My public reports have, on every occasion, stated the sedulous attention given by you in the performance of those duties, and the kindness and humanity which accompanied their execution. I may, perhaps, be thought to be travelling out of my present district, in confirming my *printed*, by *further written*, testimony of your good services, but I am so impressed with them that I rather subject myself to the imputation, than withhold what is justice to you and pleasure to myself.

"I am, Sir,

"Your obedient humble servant,

"W. J. WILLIAMS,

"Home Inspector of Prisons.

"P. N. Scott, Esq."

We learn that a proposal was made that a retiring pension should be granted to Mr. Scott, but was not entertained, from the circumstance that the office is an annual appointment. There was, however, a general feeling of regret expressed by the magistrates at their supposed inability to reward the humane, the skilful, and as the Reverend Canon Wodehouse expressed it, the "generous," devotion at a salary manifestly inadequate and unremunerative, with which Mr. Scott had so long discharged the duties of his office. The chairman of the Court, however, recommended that the friends of Mr. Scott should make a representation to the Home Secretary of the circumstances of the case, and moved that a letter should be written and signed by the chairman on behalf of the Court, in aid of such representation.

The granting of retiring pensions to meritorious public officers for long and faithful services is no anomaly in the history of this country, and we will venture to entertain the hope that the Government will not be indisposed to seize the present opportunity, not only of rewarding valuable services, but also of discharging a long-standing debt of gratitude, due to Mr. Scott, for the prevention of an act of that most fearful of all public horrors—judicial murder.

Mr. Scott's efforts in saving the life of Mary Ann Wright, when under sentence of death, are well-known; and the case not only offers "a curious parallel" to that of Mary Anne Hunt, as observed by one of our contemporaries, but, by the precedent then established by him, was probably a leading cause of the attention which has been so satisfactorily devoted to that case.

Review.

On the System of the Great Sympathetic Nerve. By C. RADCLYFFE HALL, M.D., M.R.C.S., &c., &c. Parts 1 and 2. 8vo. pp. 163, with illustrations on copper.

The prevailing ideas on the ganglionic system of nerves are vague and indefinite. Loose and floating notions that they are in some way concerned in general nutrition and secretion, or in the movements of the involuntary muscles, or in cutting off sensation from the viscera, or in producing general harmony of action between related parts, and between one part and the rest of the system, evince the importance attached to the ganglia, and at the same time the inexactness of our acquaintance with their real influence, the mode in which this is elicited, and the laws which regulate its operations. The aim of the work before us is to render our knowledge of the ganglionic system more exact and precise. Commencing his inquiries with a series of minutely narrated experiments, the author deduces from these, certain definite conclusions respecting the function of the ophthalmic ganglion, and the mode in which it is exercised. Having thus obtained exact data as regards one ganglion, he proceeds to apply them to elucidate the physiology of the ganglia in general. In considering his subject, the author takes a comprehensive range, and draws facts largely from structural and comparative anatomy, and from pathology. He takes pains to prove his position step by step as he goes on, and usually sums up in a few brief statements at the end of each argument, the conclusions at which he has arrived. This mode of summing up at the end of an argumentative disquisition is adopted by many of the most systematic foreign writers, and certainly possesses several advantages. In the first place, the

reader who is disinclined to study for himself an abstract question, may arrive at the conclusions without wading through the detail; secondly, the reader who doubts the validity of the arguments has the inferences of the writer presented to him in a tangible form for acceptance or rejection; lastly, by no means the smallest recommendation is that it compels the author to understand his own meaning.

The views entertained by Dr. Radclyffe Hall may be stated as follows:—The ganglionic nerves do not confer upon the part they supply, any capability of nutrition or secretion which it did not possess already, but merely stimulate it to the more active discharge of its natural function. For example, the organic nerves of the liver excite the secretion of bile, those of the kidney, the elimination of urine; but theoretically considered, either organ has the power of secreting its special product just as well without the nerves as with them. Concerning the nature of the ganglionic force nothing is known, but it is assumed to be precisely the same in all the ganglia, and the same in the ganglia as it is in the brain and spinal cord, "the difference in result being due to inherent difference of vital endowment in the molecule subjected to nervous influence." Thus, the same kind of force which, when conducted by a motor nerve from the spinal cord to muscular tissue, excites contraction, would, if conducted by an organic nerve from a ganglion to a gland, excite that gland to increased secretion. Every ganglion, with few exceptions, is a compound body, consisting of a spinal element, a cerebral element, and of ganglionic cells. The spinal and the cerebral elements are merely transmitted nerve-tubes, and although essential in maintaining the relationship of the ganglion to other parts, are but accessory constituents of it as a nervous centre. All the nervous force which originates in the ganglion belongs exclusively to the proper ganglionic element, viz., the grey cells, and is conveyed to its destination solely by the grey nerves which arise from them. The real destination of these grey purely ganglionic nerves has yet to be decided, but in the mean time it is assumed that every organized molecule in the body which is not already supplied by a nerve of sensation or of motion, nor yet so placed as to be exposed to the influence of the nerve-cells themselves, is related to a grey organic nerve in such a way as to be brought under the control of a ganglion. The nervous force being considered to be the same kind of stimulus in whatever centre generated, nothing would be gained by distributing ganglionic nerves to the points where cerebro-spinal nerves terminate, since any influence exercised over nutrition by the former, might be equally well fulfilled by the latter on the molecules which lie in close proximity to their termination. Hence, Dr. R. Hall conjectures that the sentient papillæ, the muscles, and also the substance of the nervous tissues themselves, do not receive any purely ganglionic nerves. As grey nerves do not terminate in muscles, mere ganglionic action never occasions muscular contraction; but the spinal nerve transmitted by the ganglion, if a motor one, most frequently excites muscular movement at the same time. On the circumstance of the transmission or non-transmission of motor nerve-fibres, the author founds his division of the ganglia. The simple or single ganglion consists of grey cells and grey nerves only. In the spinal or double ganglion, impressional nerves are superadded; and in the sympathetic or triple ganglion, both impressional and involuntary motor nerves pass through the bed of ganglionic cells. The term "impressional" is used by the author to signify all the non-motor portions of a cerebro-spinal nerve; impressibility being an attribute common to cerebral fibres of sensation and of spinal excitor fibres, both of which are related to the ganglia in a similar way. Wherever the cerebral portion is transmitted, the spinal is likewise, and both without doubt must affect alike the ganglionic cells. It is indeed inferred that all the cerebro-spinal nerves which pass through a ganglion are capable of reacting upon it equally, so as to call forth the action of its cells, whether the nerve-tubes transmitted be sensory or motor, purely spinal, or purely cerebral.

"Hence, in a sympathetic ganglion, the grey cells and nerves are submitted to a double excitement. Stimulated on the one hand by the impressional, on the other by the motor nerves, organic activity corresponds both to the impression made, and to the movement which results. In this, as in every other arrangement of nervous mechanism, the final cause is two-fold,—perfect obedience to a normal stimulus; perfect protection from abnormal irritation. By the response of the sympathetic ganglion to the impressional nerve, defensive mucus is instantly poured out; by its further response to the motor nerve, the mucous channel becomes still more lubricated, whilst the cause of irritation is passed on. In this view the cord is made the key-stone of the arch in the action of every compound ganglion; and it generally is so, because increased ganglionic action in most instances responds to stimulation of some surface, and the grey are not surface-nerves."

The spinal ganglia having no motor constituent, respond to excitement of the impressional nerves only. "An impression on the skin stimulates the cutaneous nerve at its periphery. The excitement affects the entire length of the nerve, and where the white tubes separate from each other to inclose the grey cells of the ganglion, they impart the excitement to these cells. Thus excited, the grey nerves of the ganglion cause increased organic activity in the part to which they are distributed, which is always the same as that which the corresponding impressional nerve supplies. The result may show itself in mere attraction of blood to the capillaries, (rubefaction from friction,) or in secretion, (sweating or vesication.)"

From considerations respecting the ciliary ganglion, Dr. R. Hall infers that "during ordinary excitement the ganglionic nerve-vesicles have not the power of exciting to action the white nerve-tubes which lie amongst them in their passage through the ganglion." The excitement of one transmitted nerve-tube therefore may be imparted to the cells of a given ganglion, without necessarily affecting any other nerve-tubes transmitted by the same ganglion. "This, which is an important law, is proved by the structure of a complicated ganglion, such as the superior cervical, as distinctly as it could be by the most accurate experimental investigation, were the question open to complete solution by such means.

Unless the white tubes which pass through a ganglion do influence it, of what use would be their transmission? Unless all (whatever their functional endowment,) influenced it alike, would there not be some difference discernible in their relative arrangement? and unless each nerve would act on the ganglion without exciting its fellow white nerves, would not strange confusion of action result? When gastric excitement, for example, through the medium of the *par vagum*, acted on the superior cervical ganglion, stimulated the *nervi molles*, and distended the capillary system of the face, producing heat and flushing, if the excitement spread to the other nerve-tubes transmitted, we should have always, and of necessity conjoined, the muscular actions presided over by divisions of the facial, hypoglossal, spinal accessory, and upper cervical nerves, in addition to a conjoint excitement of the transmitted impressional nerves. The influence of the transmitted tubes on the ganglionic cells is deducible again from the double gangliation of several important nerves. Unless it can react on the grey cells, why is a motor tube so carefully excluded from a spinal ganglion which supplies parts, whose organic activity would be injured by direct, and therefore constant, connection with muscular movement, whilst it is always admitted into a sympathetic ganglion, which governs organic processes constantly under the influence of muscular contraction? The lower ganglion on the vagus, on the glosso-pharyngeal, the various subsidiary ganglia on the branches of the fifth, exist, not because the ganglia on the roots of these respective nerves could not have furnished organic nerve-force sufficient, but because a portion only of the nerves must have its supplied parts associated with muscular action; whilst the remaining and larger portion of the nerves is distributed to parts not constantly under the influence of muscular movement. For the same reason are the ganglia on the spinal nerves so accurately restricted to the posterior roots. The anterior motor roots avoid the spinal ganglion, not because their voluntary power would be checked by the mere circumstance of their passing through it, but because the uncertain, unequal, irregular action of a voluntary nerve would greatly interfere with the functions presided over by the ganglion. For the same reason it may be, are spinal ganglia necessary at all to constitute centres distinct from the cord, and sympathetic ganglia to constitute centres distinct from both, since in man, (as we found in the invertebrata,) nervous centres are amalgamated or disjoined, according as the functions governed are connected or dissociated. But for this, the sympathetic vagus, and glosso-pharyngeal, would not need three separate, but similarly constituted, ganglia, lying side by side, nor would the eye require an especial ganglion, whilst the lacrymal gland does not."

The passage above may be taken as a fair specimen of the mode in which the author seeks to educe general principles from the inferences he has obtained from his experiments.

To the reaction of the cerebro-spinal nerve-tubes upon the grey cells of the ganglion through which they pass, Dr. R. Hall applies the term of "synergetic action," and this he considers to be the only mode of action of which the ganglion is capable, so far as the white nerves are concerned. He considers it certain that excitement can spread from one ganglion to another directly through the grey nerve of inter-communication, which is always found to connect one ganglion with another, and deems it probable that "peripheral stimulation of a grey nerve may occasion change of action in the ganglionic cells, and in virtue of this change have its own influence over capillary and molecular actions affected, distinct from and independently of any excitement of spinal or cerebral nerve-tube."

A reader unaccustomed to reflect on such subjects may find it difficult to realize the full signification of these general views when presented in an abstract form; but illustrated by direct application to individual ganglia, they appear to be sufficiently simple and intelligible.

Having concluded the first part with an exposition of the general laws of ganglionic action, the author devotes part second to the intervertebral ganglia, which are considered under the heads of their comparative anatomy, structural connexions, and supposed physiological and pathological relations. Setting out with this acknowledgment, that he does not deem the physiology, nor consequently, the pathology of these numerous ganglionic centres established, he founds his conclusions chiefly on anatomical arrangement, and on analogical reasoning. He appears desirous of giving to the principles laid down in the first part a practical application, and derives his illustrations from the most familiar conditions. We have successively passed under review the part played by the spinal ganglia in the various instances of sympathy between the skin and the mucous membranes, in perspiration, heat of surface, cutaneous reaction, the effects of hot and cold applications, counter-irritation, palsy with increase of temperature, hysteria and spinal irritation. The usual summary of conclusions follows.

Amongst the many debateable points interesting to the physiologist, which come under discussion in various parts of the work, and on which the author has something new to offer, we may notice the following:—An explanation is given of the previously unexplained fact that section of the fifth nerve is invariably followed by dilated pupil in dogs and cats, and by contracted pupil in rabbits and guinea-pigs. The opinion of Valentin that a special nerve presides over the dilating action of the iris, and that this nerve is furnished by the cervical flexus, is shown to be untenable. The influence which the fifth nerve exercises upon vision is referred to the power possessed by this nerve of modifying the circulation in the capillary system of the retina through the medium of the ophthalmic ganglion. The structure of the ganglia both spinal and sympathetic, is demonstrated by the microscope to be identical in kind with that of the brain and spinal cord. The direct origin of nerve-tubes in nerve-cells partially established before, is confirmed. The double mode of development of primordial cells by budding, or by bursting of the parent cell, which recent researches prove to be so general in the generation of vegetables and of the lower animals, is well illustrated in the highest tissue of the highest animals by its occurrence in the cells of all the nervous centres, (p. 60.) The varicose condition of certain nerve-tubes ordinarily ascribed to artificial interference, or to *post-mortem* change, is considered to be the normal form, and has its special office suggested. The zig-zag flexions in which the

nerve-tubes are arranged in their sheath are particularly described, and their presumed use assigned. The extensively-received opinion that the ganglia are excito-motory centres, in which the reflex actions of the involuntary muscles originate, which has recently been supported experimentally by Volkmann, is discussed at considerable length, and opposed by various arguments founded on anatomy and on experiments. In examining into the manner in which the ganglia are influenced by emotional states of the mind, reasons are given for assuming that all nerves act centrifugally only; that the nervous force is conducted outwards from its source in the grey cells of a nervous centre as much in a nerve of sensation, as it is generally admitted to be in one of motion; but this assumption the author expressly states is in no respect essential to the remainder of his views, and may be received or not, without affecting the rest. The decussation of the greater part of the tracts of common sensation, corresponding to the decussation of the common motor tracts, is figured as occurring in the *pons Varolii*, and illustrated by three finished engravings of the brain in the dog and sheep. Agreeing precisely with the description given by Mr. Solly, in the new edition of his work subsequently published, from the coincidence of the observations thus independently made, the assertion of this anatomical fact derives considerable support.

We shall conclude this catalogue *raisonnée* by remarking, that in the tabular classification of the ganglia given at the end of part first, we find one which is new to us, specified as being fixed on that part of the *portio dura*, within the Fallopian duct, from which the *corda tympani* takes its rise.

The illustrations are drawn by the author from nature, and neatly engraved on copper. We have much pleasure in recommending the work to the notice of our readers.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

ABSTRACT OF A PAPER ON

THE PATHOLOGY OF BURNS.

By John Erichsen, Esq., F.R.C.S.
Lecturer on Physiology at the Westminster Hospital.

The following abstract of Mr. Erichsen's paper will, it is hoped, direct the attention of the members of the Association to the morbid anatomy of burns, and the necessity of great attention to the *internal* treatment of those accidents :—

Mr. Erichsen begins with stating that the "frequent occurrence of structural changes in the organs contained within the head, chest and abdomen, as a consequence of severe or extensive burns, is a fact familiar to all surgeons; but the precise nature, comparative frequency and immediate cause of the different lesions that may occur in these injuries, have not" as it appears to him, "been as yet, ascertained with a proper degree of precision;—no sufficiently extensive series of observations having been made on the subject." In order to clear up these points Mr. Erichsen, has collected together and arranged in a tabular form; all those *fatal* cases of burns that he could find carefully reported in different periodicals and treatises, or that have fallen under his own observation. The results of an analysis of the *post-mortem* appearances observed in these cases are given in Mr. Erichsen's paper. The table, (which occupies six pages,) gives the name, age, sex of the patient; the degree of the burn, and the pathological appearances in the head, chest and abdomen; the day after the burn on which the patient died, and references to the source from which each case was ascertained. The cases are arranged under three heads, namely,—1st., those that died during the period of *congestion;* 2ndly, those that died during the period of *inflammation;* and, 3rdly, during the period of *suppuration.*

Class 1.—The first period, (that of congestion,) is limited to the first 48 hours, in which death occurs before inflammatory action comes on; or, at all events, is fully established. On examining the table it will be found that the number of cases contained in this class amounts to sixteen. Of these, the brain and its membranes were found congested, with more or less serous effusion into the ventricles or arachnoid in fifteen cases.

The contents of the cranium not examined in	1
Lungs congested, with more or less redness of the bronchial membrane, and effusion into the pleura, in	8
Lungs hepatized in	1
State of the thoracic viscera not mentioned in	2
Thoracic viscera healthy in	5
Abdominal organs healthy in	2
.. .. not mentioned in	2
.. .. congested more particularly in the mucous membrane of the stomach and ileum, in	12

In one of these last cases there was air in the peritoneum; in four others there was serum effused, and in one that membrane was dry. Thus it will be seen that in all the patients who died during the period of congestion, there were found sufficient structural lessions, more particularly of the brain and its membranes, to account for death,"

Class 2.—The cases contained in the second class, the period of inflammatory re-action and inflammation, extend over a larger space of time, from the second day to the end of the second week; they are necessarily more numerous than those of the first class, being twenty-five in number.

Of these, the state of the brain and its membranes was not mentioned in eight cases; of the remaining seventeen cases,—

There was congestion or evidences of inflammation, with more or less of effusion of serous fluid, principally of a bloody character, in	11
There was serous effusion only in	3
A healthy condition in	3

The state of the *thoracic* viscera is not mentioned in six cases. Of the remaining nineteen,—

There was congestion (probably in many instances inflammatory,) in the lungs, with more or less effusion of serum or lymph in the pleuræ, with redness of the bronchial mucous membrane, in 10
Lungs hepatized in 5
Lungs, &c., healthy in 4

The state of the abdominal organs not mentioned in three cases. Of the remaining twenty-two,—

There was increased vascularity chiefly of the mucous membrane of the small intestines, with, in some cases, evidences of peritonitis, in 11
Ulcers in the duodenum in 6
Abdominal organs healthy in 5

Thus it will be seen, that the cases in this class differ in some very important respects from those in the preceding one. The cerebral lesions are found to be not quite so frequent, but when they do occur, they present more unequivocal evidences of inflammatory action. The lungs are rather more frequently affected, and show decided marks of pneumonia, or of intense bronchitis, as manifested by the former disease having, in several cases, advanced to hepatization, and by the inflamed state of the bronchial membrane, which is usually coated with a thick frothy mucus. Appearances indicative of pleuritis are also by no means uncommon in those cases that prove fatal during this period. The most marked characteristics of it, however, are to be found in the lesions of the abdominal organs, which, although not so frequent as in the stage of congestion, are unquestionably of a far graver nature; that very remarkable and serious *sequela* of burns perforating ulceration of the duodenum being found in no less than six of the 22 cases, or one of every 3.6 deaths that occur during this period. In one instance ulceration of the duodenum was found in a patient who died on the fourth day after the infliction of the injury, the only case on record, I believe, in which this lesion has been noticed at so early a period. Besides the lesion just mentioned, there are abundant evidences of the existence of peritonitis, and of congestion (very probably inflammatory,) of the intestinal mucous membrane of those who die during this period.

Class 3.—The cases contained in the third class (those in which death occurred during the period of *suppuration*,) are nine in number; and these we shall find to be distinguished by several interesting peculiarities.

The *brain* and its membranes were not examined in four cases. Of the remaining five,—

There was effusion with congestion in 1
There was effusion without congestion in 2
Preternatural dryness in 1
Healthy condition in 1

State of the *thoracic* viscera not mentioned in two cases. Of the remaining seven,—

There was congestion of the lungs, with effusion into the pleuræ, in 2
Purulent infiltration of the lungs in 2
Hepatization of the lungs in 1
Recent lymph effused into the pleuræ in..... 1
Lungs healthy, but exsanguine, in 1

The condition of the *abdominal* viscera not mentioned in two cases. Of the remaining seven,—

Inflammation of duodenum, and congestion of ileum, in 1
Congestion of ileum in 1
Cicatrized ulcer in stomach: otherwise healthy, in 1
Healthy in 4

Thus it will be seen that in the third class of cases lesions of the lungs are the most common;—of the brain, least; whilst those of the abdominal viscera are but of infrequent occurrence.

Of six cases in which morbid changes were found in the lungs or pleuræ, one died on the 24th, and the remaining five between the 30th and 39th days. The pneumonia will at this period be found to be in a more advanced stage, having, out of the five cases in which it occurred, gone on to purulent infiltration in two, and to hepatization in one. There is one case of peculiar interest in this class,—viz., that in which a recently cicatrized ulcer was found in the stomach, which lesion must, like the duodenal ulcers, have occurred during the second period, the patient dying in the third of pneumonia and bronchitis.

Thus then it will be found, that of the cases that occurred during the first period,—

The cerebral organs were diseased in..... 15 out of 15 or 100 per ct.
The abdominal organs were diseased in.... 12 out of 14 or 85.7 per ct.
The thoracic viscera were diseased in .. 9 out of 14 or 64.2 per ct.

In the second period the comparative ratio is as nearly as possible the same; if anything, the cerebral organs are a little more frequently affected.

The brain and its membranes diseased in .. 14 out of 17 or 82.3 per ct.
The thoracic viscera diseased in..... 15 out of 19 or 78.9 per ct.
The abdominal organs diseased in ..... 17 out of 22 or 77.2 per ct.

In the third period—

The thoracic viscera diseased in..... 6 out of 7 or 8.57 per ct.
The cerebral organs diseased in ..... 4 out of 5 or 80 per ct.
The abdominal viscera diseased in ..... 2 out of 6 or 33.3 per ct.

On taking the total amount of the whole of the cases, and reducing it to decimals, it will be found that,—

The cerebral organs were diseased in .. 33 out of 37 or 89.1 per ct.
The thoracic viscera diseased in..... 30 out of 40 or 75 per ct.
The abdominal viscera diseased in ..... 31 out of 42 or 73.8 per ct.

The period at which death may be expected to occur

varies, necessarily very considerably, according to the nature of the individual case, the extent or severity of the burn, and the age or constitution of the patient. On taking, however, the aggregate of the 50 cases, without reference to these modifying circumstances, we shall find that 33 or 66.0 per cent. prove fatal during the first week. Of these 33, no less than 27 died during the first four days, and the remaining six on the three following days.

Of the 17 that were left—

8	died during the	2nd	week.
2	..	3rd	..
2	..	4th	..
4	..	5th	..
1	..	6th	..

Thus it will be seen that the greatest number of deaths occur during the first few days, in the stage of congestion, or whilst that condition is passing into an inflammatory one. After this period the mortality diminishes progressively until the fifth week, the period of suppuration, when the chief dangers to be apprehended arise from exhaustion, purulent infiltration of the lungs, and inflammation of those organs.

The relative frequency with which different organs are affected at different ages, varies somewhat, though but to a very trifling degree. On dividing the whole of the cases into two classes, those which occur below the age of puberty or fourteen years, and those which occur above that age, it will be found, that 29 cases fall into the first division, and 20 into the second,—the age not being mentioned in one.

Of the 29 cases, or those that occurred below the age of puberty—

The brain, &c., not examined in	8	
.. .. healthy in	4	
.. .. diseased in ..	17	or 80.9 per cent.
The thoracic viscera were not examined in	5	
.. .. healthy in	6	
.. .. diseased in	18	or 78.2 per cent.
The abdominal viscera not examined in	2	
.. .. healthy in	6	
.. .. diseased in	21	or 77.7 per cent.

Of the 20 cases that occur above the age of fourteen—

The brain and its membranes not examined in	5	
.. .. healthy in ..	0	
.. .. diseased in ..	15	or 100. per cent.
The thoracic viscera were not examined in	3	
.. .. healthy in ..	3	
.. .. diseased in ..	14	or 82.3 per cent.
The abdominal viscera were diseased in	13	or 81.2 per cent.
.. .. healthy in	3	
.. not examined in	4	

Mr. Erichsen then proceeds to point out the analogy between the morbid appearances observed after death from burns, and those which are observed in death after some of the eruptive febrile diseases, such as small-pox, measles, scarlatina, and erysipelas, in which the functions of the skin, as an eliminating organ, are more or less extensively suspended.

Both after burns and the eruptive febrile diseases, "nothing is more common than to find the mucous membrane of the stomach and bowels congested or inflamed, the follicles being enlarged and prominent; together with evidences of meningitis, whether consisting in the deposition of lymph, or the effusion of serum, with more or less congestion of the cerebral substance. Inflammation of the bronchial membrane is also of very frequent occurrence, and inflammatory congestion of the tissue of the lungs in its different stages is by no means rarely met with. Thus, then, the lesions that occur, as a consequence of the eruptive febrile diseases, are very similar, in many respects, to those that are found in fatal cases of burns."

"When we consider that the average quantity of the cutaneous secretion amounts in a healthy adult to eleven grains in the minute, or between two and three pounds in the twenty-four hours, (Seguin,) we cannot suppose that this secretion should be suddenly arrested to the extent of one half, or even more, as it necessarily must be, when a corresponding portion of the skin is injured by the action of caloric, without its being absolutely necessary that one of two things should happen; either that an antagonistic secretion, to a corresponding amount, be set up from some other tissue or organ, or else that a degree of plethoric distension of the whole vascular system, giving rise to congestions of internal organs and membranes, and effusions into serous cavities, take place. Now, the first does not occur in most cases of burns to a sufficient extent, but the system becomes hyperæmic. Congestions ensue in the mucous membranes, partly from the condition that is common to all the tissues, and partly from the increased afflux of blood that is always attendant upon increased functional activity of a part. The brain and lungs, as well as other large organs, occasionally become engorged, effusion of a more or less bloody fluid takes place into the different serous sacs, the arachnoid amongst the rest, and death ensues from causes that are themselves the immediate effects of suppression of the natural secretion of the skin. By this means we may account for the occurrence of death in the earlier period of burns, before there has been time for inflammation to be lighted up, and also for the fatality of those injuries of this nature, that are extensive but superficial,—burns of the first and second degree,—in which cases the functions of the skin injured are entirely and suddenly arrested.

The practical bearing of the facts that have been mentioned in the first part of this paper, on the constitutional treatment of burns, is sufficiently obvious. If, as has been stated, the immediate cause of the occurrence of internal congestions and consecutive inflammations be the suppression of the cutaneous transpiration to a greater or less extent, and consequent retention in the system of a large quantity of fluid that ought to pass off by the skin, we should, in order to prevent the supervention of these secondary diseases, endeavour to set up such a drain on the system as would, as rapidly as possible, compensate

for the arrest of the secretions of that tissue, and have a tendency to restore the balance of the circulation, disturbed by the accumulation of an unusual quantity of fluid in the system. This may either be effected by the employment of diuretics, so as to induce an increased action of the kidneys, by guarded blood-letting, carried to such a length as the powers of the patient would allow, or else, (what would be better, if time and the nature of the case would admit of it,) by encouraging the process of suppuration as quickly as possible. It is a question whether diuretics or blood-letting might not be of advantage in preventing internal congestions in extensive *superficial* burns, in which the suppurative process would, probably, not be established; the injury not being sufficiently deep for that purpose. On the other hand, when the burn extends to a greater depth, if there be no immediate occasion for the loss of blood, from the actual occurrence of visceral mischief, the process of suppuration should be hastened and maintained, consistently with the powers of the patient, as a useful drain, and as perhaps the best mode of relieving the system from the pressure of the fluid retained within.*

Mr. Erichsen then points out the necessity of watching carefully for the occurrence of any cerebral symptoms in cases of burns, and of meeting them with vigorous measures, on account of the rapid progress of the inflammatory congestion and effusion in such cases. He says that there can be no doubt that this may be frequently accomplished by prompt venesection or bleeding; and he quotes a case which occurred in Mr. Cooper's practice, at University College Hospital, in a child of six years of age, who was admitted "for an extensive burn, (of the first, second, and third degrees,) of the upper part of the trunk, arms, and face. Symptoms of encephalitis, followed by violent convulsions, and complicated with an extensive bronchitis, set in, a few days after admission; for these she was bled twice in the jugular vein, and treated in an active antiphlogistic manner, and notwithstanding the injury for which she was admitted, and the serious nature of the affections with which it was complicated, she recovered perfectly, although there can be little doubt, that had less energetic and prompt measures been had recourse to, a fatal result would have occurred. A somewhat similar case is reported in the *Lancet*, by Mr. Thomas: it occurred at the Middlesex Hospital. Next to the brain, it is necessary to observe the condition of the lungs; any symptoms of mischief in them, however trifling, must be anxiously watched, and promptly treated. If mischief is perceived in the chest, as active treatment as the case admits of must be adopted to meet it. Mr. Erichsen puts in a caution against forgetting the reduced condition of the patient after the burn, and the need he will have for strength to support him through the suppurating stage. He thinks there is greater risk from inactive treatment in the early stages of visceral inflammation caused by burns, than from too great a depression of the vital powers at a more advanced period, from too energetic depletory measures. It is easier "to build up the strength" than to "check the course of inflammation without due depletion."

Mr. Erichsen concludes with the following words:—"On taking, then, a general review of the constitutional treatment of burns, it may be stated that the first object should be to relieve the system of the abnormal quantity of fluid that must have accumulated in it, in consequence of the arrest, to a greater or less extent, of so important a secretion as the perspiration. This may be accomplished either by the administration of diuretics, by guarded blood-letting, or by encouraging the process of suppuration, if it be deemed prudent to wait till this be established. Secondly, that any appearance, however slight, of the supervention of inflammation in the organs contained within the head, chest, or abdomen, should be watched with the utmost anxiety, and treated, if it do occur, as the circumstances of the case will admit. And, thirdly, that the process of suppuration should be maintained or arrested with a due regard to the state of internal organs, and the condition of the powers of the system."

* Mr. Crompton will be thankful for any practical facts bearing on the above remarks of Mr. Erichsen. Dr. Kentish recommended *saline* purgatives in burns. He says (at page 122, 2nd edition of his Treatise on Burns,) "As secretion (from the burnt surface,) frequently appears on the third day, the necessity for stimulants will cease, and they must give way for a different mode. *Saline purgative* medicines should be given after secretion takes place, both with a view of tranquillizing the system under the inordinate action excited by the stimulants, used at the outset, and to lessen the secretion of pus." At page 128, he says, "If the secretion of pus should continue profuse when the eschars are detached, *a counter-irritation upon the mucous membrane of the intestines will be necessary. A brisk cathartic with calomel and jalap, according to the strength of the subject, given once or twice a week, will astonishingly facilitate the cure.*"

Mr. Henry Earle confirms the above statement as to the value of purgatives. At page 26 of his tract on Burns, he says, "Diarrhœa sometimes supervenes, and is occasionally beneficial when the discharge is very copious. From observing the occasional good effects resulting from spontaneous diarrhœa, when the discharge was profuse, in accelerating the healing process, Dr. Kentish strongly recommends the free use of purgatives under such circumstances, *and I have known them very useful.*"

COMMUNICATIONS ON BURNS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In the last number of your Journal, at page 44, it is stated that clothing is said to be rendered fire-proof, by being steeped in alum-water. I have heard the same observation made by some friends. It may be well to state that I have steeped cotton and woollen in a saturated solution of alum, and that they are not thereby rendered fire-proof, on the contrary, they take fire readily. I now forward you the subjoined communications:—

By Dr. HERBERT BARKER, of Bedford.

As dresser and House Surgeon under Liston, whose premature death the profession now so keenly laments, I had ample opportunities of observing the good effects of the external application of flour; and so convinced was this distinguished surgeon of the superiority of

that over all other applications, that he proscribed everything besides. His mode of applying it was by means of the common dredger, taking care to cover every part of the affected surface. He enjoined the repeated application of the flour to those parts where the discharge of serum oozed through the first applied portions of the powder. He was also careful not to disturb the application until it had completely caked together, and had become loosened by the discharges underneath.

This is the plan of treatment which I have since invariably followed. The application of the flour is very soothing, and in a few cases in which other modes of treatment had been previously resorted to, the application of the flour has speedily been followed by the most marked relief of pain, and diminution of the consequent constitutional irritation. Flour of the finest and best quality should be used; it should be lightly and freely applied, and the complete exclusion of the air should be secured by repeatedly dredging the parts where the escape of serum takes place; perfect quiet should be enjoined, and the application should be allowed to remain until thoroughly undermined by the discharges. Several days, in some cases, will be required to effect this, when the masses of caked flour may be readily removed. I have then had recourse to water-dressing, by means of lint and oiled silk. Cicatrization, if tardy, has been promoted by the substitution of a weak solution of sulphate of zinc for plain water, and exhuberant granulations have been effectually repressed by lightly rubbing over the surface a smooth piece of sulphate of copper. The most important indication in these cases is the alleviation of pain and constitutional irritation, by the thorough shutting out of the air; and no application appears to me so effectually to accomplish this as the application of fine flour. It would seem to act less as a foreign body, and better to supply the place of the cuticle, than any other application with which I am acquainted. Indeed, such good reasons have I had to be satisfied with this mode of local treatment, that, unless the weight of evidence which you may collect should greatly preponderate in favour of some other application, I shall not be induced to try any other.

With regard to the constitutional treatment, I have little to say more than that, in my hands, the *muriate of morphia* has been found to be the most eligible form of anodyne. It is followed by less inconvenience than any of the crude opiates. Stimulants have been found to be very beneficial in some cases of early depression of the vital powers, but it must be confessed that the greatest caution is required, and that it would be difficult to lay down precise rules for their administration. I have generally used from the first a liberal allowance of good beef-tea, and castor oil is the only laxative I have dared to administer in these cases, unless contra-indicated by nausea and vomiting.

The position of the injured parts during cicatrization should, of course, claim the greatest attention in reference to the prevention of deformity. So gradually and almost imperceptibly, yet so powerfully, will the process of cicatrization lead to the contraction of parts, that the surgeon cannot be too careful to guard against it. Where the limbs and surfaces of the joints have been involved, I have had recourse to the careful adjustment of splints, with considerable success, but it is necessary to keep them applied much longer than at first sight would appear to be required, in consequence of the *after-contraction* of the cicatrized surface.

Of attempts to relieve deformities from cicatrization, I cannot speak favourably, having made the attempt in one case of union of the lower lip and chin to the front of the neck, but without success. A very successful case of this kind, however, is described and figured in Fletcher's "Surgical Notes and Illustrations."

In conclusion, the application of flour to burns and scalds is probably that which could be more promptly and readily adopted by the public than any other. I would suggest, if the medical attendant be not within immediate call, that the patient be placed upon a firm bed or mattress, with the head somewhat elevated, and the injured parts of the surface uppermost; if the limbs be involved in the injury, that they be placed in a straight position; fine flour should then be perseveringly sprinkled over the affected parts by means of a dredger, so as thoroughly to cover the surface. Should the injury be severe, and the distance from the surgeon so great, as to render it impracticable for the case to be seen early, strong beef-tea may be freely administered, but in no case should stimulants be given, unless under medical direction. These are all the instructions on the subject which I consider as necessary for the public, and it is my decided opinion that the immediate application of flour in the manner directed would be followed by much less suffering than of any of the thousand and one popular remedies which we are accustomed to meet with.

By W. Newnham, Esq., of Farnham,

From the first time of my dressing for Sir Astley Cooper, at Guy's Hospital, till the present moment, I have observed that a certain amount of burn or scald proves fatal under any method of treatment; and *that* especially when the sensitive nerves of the skin have been exposed. Thus a severe scald will prove more rapidly fatal, than an equally extensive burn, *provided* that the latter had been gone beyond the stage of vesication and has disorganized the true skin. I should say, therefore, that my practice has been founded upon this distinction,—in the former state, to prevent as far as possible the exposure of the nerves; and in the latter, as early as constitutional circumstances permitted, to stimulate the skin to throw off the disorganized structure.

1. I have not seen Dr. Kentish's plan extensively tried, and when I have seen it, the result has been unfortunate.

2. In burns of great extent, such is the depression of the powers of life, that I question the propriety of cold applications; in burns of a small surface, there may be no objection, though,—

3. I think the dressing by cotton far more useful,—even more so than flour, because it more effectually covers and protects the exposed nerves.

4. *Immediately* after burns, &c., I have usually found a gentle stimulant desirable, especially ammonia rather than alcohol, and the subsequent medicinal treatment must be determined by the degree of re-action, and the kind of constitution in which it is taking place; each individual case being decided upon its own merits.

5. *Extent* rather than *situation* I have found to be the principal cause affecting the result; at the same time there are situations of the body where the nerves are more exquisitely sensitive, or are more liable to irritation, or are supplied in an especial manner, which would, of course, *cæteris peribus*, add to the constitutional irritation and consequent danger.

6. I have no experience beyond that of care during the process, and for a considerable time after the completion, of cicatrization.

7. I have no personal experience.

8. The grounds of *prognosis* I have already given; and I think I have seldom failed to judge correctly as to the event, from taking as my guide the extent of burn or scald, and the immediate amount of constitutional depression.

9. On this question I have no personal experience.

10. I should say extinguish the flames instantly, by enveloping the patient with a rug, blanket, carpet, great-coat, or such-like article; and then apply cotton-wool, to secure the burned parts from exposure.

11. I should here only refer to general principles.

12. I have none to give.

By Dr. Glass Black, of Torquay.

As I observe by your letter in the *Provincial Medical and Surgical Journal*, that you are anxious for the accumulation of facts, I beg to throw out one hint, which I have not seen noticed, on the use of cotton-wool, which I have employed for many years in the treatment of burns and scalds. It is this, that it should never be *removed* from the *surface* of the sore; the outer portions which are saturated with the discharge may be cut off, and clean applied, but that covering the wound *never*. In the observation of this caution, I believe *mainly* depends the superiority of this remedy to any other application. That it is preferable to flour, was evinced by the following case:—A tradesman's wife scalded her instep with boiling water, and covered it well with flour; a few days afterwards, on going to the house to see her husband, she mentioned it to me, and complained that the wound was very painful, and would not heal. I recommended the whole to be removed, and the part covered with cotton wool, as soon as it could be procured, on doing which the pain was instantly relieved, and the ulcer quickly healed.

I hope that those members of the Association who are connected with Hospitals and Dispensaries will forward to me statements of the practice adopted in their respective institutions, and its results. I wish it to be borne in mind that there will be only about twelve more publications of the Journal prior to the Annual Meeting.

I am, Sir,
Your most obedient servant,
SAMUEL CROMPTON.

71, Grosvenor Street, Manchester,
January, 1848.

[With the foregoing communications, several others of importance were forwarded by Mr. Crompton, including letters from Mr. Wood, of Rochdale, Mr. Greenhow, of Newcastle-upon-Tyne, and Mr. Dorning, of Swinton. Owing to the space occupied by the abstract of Mr. Erichsen's valuable paper, these communications are unavoidably postponed to the next number of the Journal.]

Foreign Department.

ON POISONING BY ARSENIC.

By MM. Orfila and Jardien.

The October number of the "*Annales d' Hygiène*," contains lengthened official reports of the medico-legal investigations, which were rendered necessary by the murder of the Duchess de Praslin, and the suicide of the husband. The portion relating to this latter event contributed by MM. Orfila and Jardien, contains some points worthy of notice.

On the evening of the 18th of August, the murder having been committed on the morning of that day, the Duke was seized with vomiting, accompanied by a very small pulse, and great exhaustion. This state continued the next day, and on the 20th M. Andral was called in. He found him better, his powers having rallied, and his voice become firm. His aspect and respiration were natural, and he complained of no pain on pressure of the epigastrium. With these conditions, which seemed satisfactory enough, two remarkable symptoms were present, viz., such *extreme smallness of the pulse* that it could hardly be felt, while it was also irregular, and an *icy coldness of the extremities*. M. Andral gave it as his opinion, that although these symptoms might result from the intense moral emotions to which the Duke had been subjected, they might also be due to the ingestion of poison, and advised that all matters evacuated in future should be analysed. It seems singular, indeed, that under the circumstances in which this man was placed, his having poisoned himself should not have been the first idea that presented itself to his attendant, M. Raymond. In the evening some re-action took place, the pulse became developed and regular, but frequent, and the hands regained some warmth. On the 21st he was removed to prison, and in the evening his pulse again became filiform, and his extremities cold; great constriction of the throat, intense thirst, and meteorism of the abdomen were present; but little or no urine or stools were passed, and the vomiting had not re-appeared since the 19th and 20th. Every symptom was aggravated; the tongue and buccal mucous membrane were intensely

red, and there was a sense of burning, extending from the mouth to the anus; pulse very frequent, sometimes weak, and sometimes strong; no vomiting; two stools from enemata, and hardly any urine. From this time the patient gradually sank, but lingered on to the 24th, his intellect remaining clear to the last.

At the autopsy, the appearances rendering poisoning probable were as follows:—1. The dissemination on the inner surface of the left ventricle of a large number of small hæmorrhagic spots, produced by the effusion of blood beneath the endocardial membrane, some of these penetrating into the fleshy substance of the heart. 2. Within the large curvature of the stomach, seven large black eschars were discovered; they were clearly defined by a yellowish white border, the mucous membrane surrounding them being softened and of a deep red. The eschars did not involve the whole thickness of the walls of the stomach; nowhere did ulceration or perforation exist; the intervening mucous membrane was sound. 3. At the upper portion of the duodenum, and lower portions of the ileum, the mucous membrane was found of a deep red, inflamed, but nowhere ulcerated. The other viscera were sound.

In reference to the *eschars*, M. Orfila remarks, it would be a great error to suppose they arose from the local action of the arsenic; they in fact resulted from the absorption of the poison, analogous alterations appearing in animals that have been poisoned by introducing arsenic into the subcutaneous cellular tissue at the inner part of the thigh. Such alterations are seen when the quantity swallowed has been considerable, and especially where death has been long delayed; for when this occurs promptly after the poisoning, not only is no eschar present, but scarcely even a slight inflammation. The liver and intestinal canal, when submitted to analysis, afforded abundant proof of the presence of arsenic. M. Orfila makes some important remarks upon the different modes of operating on the liver by means of chlorine, according to the quantity submitted to analysis; and in a note lays down some rules (p. 405,) which the practical toxicologist will do well to consult.

In the two first questions put by the Chamber of Peers upon the *cause* of the death of the prisoner, and the *nature of the agent* by which it was effected, the answers given were obvious. "We had not," observes M. Orfila, "to determine what quantity might have been taken, for as a general rule, such a question ought neither to be put nor replied to. As in no case is it possible to know in what proportion the poison disseminated throughout the body exists in this or that organ; as the variations in absorption, the different modes of excretion, and the amount of evacuations, necessarily render the amount eliminated variable and indeterminable; and, as on the other hand, a portion of it is invariably lost in the operation of examining it, whatever process be followed, it is evident that the solution of this problem should never be sought, and that the only thing truly important, is the proof of the presence and the nature of the poison."

At what period was the poison swallowed? By a negligence almost incredible in such sharp-sighted persons as the Parisian police, it seems that, although the clothes which the prisoner took off on his apprehension were carefully examined and put under a seal, a dressing gown which he desired might be given him in place of the one removed, was afterwards found to have had in its pocket a phial containing arsenic! Until four in the afternoon he was surrounded with persons, and no symptom whatever of deranged health had yet manifested itself. At ten in the evening vomiting first appeared. Can we state the time which should elapse between the swallowing of the poison and the manifestation of the symptoms? There is nothing positive in this respect. Several circumstances may cause the limit to vary, and more or less retard the manifestation of symptoms. The form of the poison, the presence or absence of acid or other fluids in the stomach, the fulness or emptiness of that viscus, the rapidity or slowness of absorption, may accelerate or retard the action of the poison. In this case, the arsenic being taken in the solid form, and in a state of coarse powder, and no great quantity of liquid being swallowed with it, might not reveal its symptoms until after a certain period. But, fixing the time as remote as possible, we can scarcely admit, except under some very peculiar circumstances, that the effects could be delayed beyond three or four hours.

Is there anything in the present case to tend to the belief that another dose of poison had been taken at an epoch nearer death? No. The cessation of the vomiting on the second day might have led to the opinion that a real amelioration had manifested itself; but this was only apparent, other symptoms announcing the man to be still under the influence of the poison, such as frequent syncope, involuntary evacuations, feeble pulse, and excessive thirst. Many examples may be cited of persons dying several days after ceasing to vomit, although no more poison had been taken. "It is very common in fact" observes M. Andral, "to find in these cases the symptoms diminishing after the early vomitings, and the poison by its presence in the economy determines new accidents, which result both from the progress of the inflammatory re-action, and from the dispersion of the arsenical molecules among the various organs."

Has the action of the poisonous substance been interfered with or destroyed by any other agent? "It is by no means impossible that a narcotic may, in certain cases, by paralysing the absorbent action of the mucous membrane of the stomach, retard or even destroy the effects of such a poison as arsenic. We have shown by recent experiments, (*Annales d' Hygiène*, tom. 38, p. 199,) that by means of small doses of an opiate compound, we can thus diminish vomiting and retard its appearance, render the pains less severe, and prolong life." There is, however, no reason to believe that the prisoner took landanum or opium with the arsenic, the contrary indeed being proved by the symptoms before, and the examination after, death.—(*Annales d' Hygiène Publique*, tome 38, p. 390—412.)

General Retrospect.

PATHOLOGY & PRACTICAL MEDICINE.

SPONTANEOUS RUPTURE OF THE SPLEEN DURING THE COURSE OF TYPHOID FEVER.

This is so rare an accident, that the following case, which occurred in the practice of M. Chomel, may be considered almost unique:—

A labourer, aged 28, of robust constitution, entered the Hotel Dieu on September 10th, 1847, in the following state:—Intelligence perfect; countenance depressed; eyes dull; violent frontal headache; tongue moist and red, with a white centre; slight meteorismus, *gargouillement* in the right iliac region, with abdominal tenderness; skin dry, covered with roseate patches; pulse 100. He was bled with relief to the headache, but his other symptoms were increased. The face assumed a stupid expression, prostration ensued, and the patient had muttering delirium. He died on the 21st. The following appearances were observed after death:—

Injection of the dura mater; turbid serum in the ventricles; medullary substance slightly injected. The lungs were healthy, as also the heart. In the peritoneum *a large quantity of blood was observed to be effused; and on examining the spleen, a rent in a vertical direction indicated its source.* The tissue of the spleen was friable, in fact almost softened into a putrilage, but its envelope was firm and resistant.—*Gazette Médicale*, No. 47, 1847.

DISCHARGE OF A TOOTH FROM THE EAR.

The following curious case occurred in the practice of Mr. Coates, of Great Malvern:—A poor old man had suffered for some days from severe pain over the whole of one side of the face and head, but more intensely still about the ear. He was feverish, in great pain, and incapable of opening his mouth; the pinna and skin, lining the external meatus, were highly inflamed and swollen. Warm fomentations, poultices, and purgatives, were ordered. Two days afterwards Mr. Coates paid him a visit. He was then in great pain, and, otherwise, much in the state already described, but, in addition, there was an oozing of pus from the meatus, and almost entire closure of that passage by a whitish substance, which the patient conjectured to be a piece of onion, introduced there on the recommendation of some old woman, but which a probe detected to be bony. The patient declining to have this removed, he was recommended to continue to foment and poultice. The same night a fit of sneezing forced out the piece of bone felt by the probe, which proved to be one of the wisdom-teeth of the upper jaw; after that the man got well.—*Lancet*, Nov. 6th, 1847.

NEW VEHICLE FOR HOLDING CAMPHOR IN SOLUTION.

Sir James Murray proposes a new vehicle for holding camphor in solution in doses considerably greater and with less irritation than it has hitherto been given. It was known that camphor is insoluble in water, and that when given in almond emulsion, it very readily separates on the addition of water, and that the same separation takes place on adding water to a solution of camphor in spirits of wine. The opinions respecting the effect of camphor are various. Some describe it as a stimulant, and some as a sedative, but this difference of effect depends mainly on the quantity given. Now, Sir J. Murray found that the fluid magnesia was capable of dissolving camphor to the extent of three grains to the ounce of the solution, and that adding water to the mixture did not cause any cloudiness or separation of the camphor. An ounce of this solution contains three grains of camphor, which appears perfectly clear like water; and if anything is added to the solution capable of withdrawing a portion of the water, such as dry common salt, a rough estimate may be formed of the quantity of camphor it contains. To employ camphor as a sedative, it must be given in large doses, but it is also necessary to have it perfectly dissolved, for when free, it acts as a powerful stimulant. It is obvious, then, that given for this purpose it would not do to employ the camphorated spirit, nor will the solution in emulsion be any better, as it readily separates from it in the stomach. We have therefore, he observes, a menstruum in the fluid magnesia which answers better than any method hitherto known.—*Dublin Medical Press*, Dec. 15th, 1847.

METHOD OF REMOVING THE STAINS OF IODINE FROM THE SKIN.

The *Annales de Thérapeutique* contains an article in which it is stated that the stains of iodine may be removed from the skin by washing for a few minutes in milk. The stains must, however, be quite fresh, as, if dry, the milk has no action upon them.

SURGERY.

ERECTILE TUMOURS.

M. Fayalle (de Gûerat) proposes a new method of treating erectile tumours, which he thus describes:—The necessary instruments are, a number of needles of different sizes, some waxed ligatures, consisting of three threads each, and a nippers to cut the needles. The operation is to be performed in three parts. First, the thickness of the tumour being ascertained, a needle is introduced through the sound skin a line and a half from the margin of the tumour; this is followed by a second, which is tangent to the circumference of the tumour; a third needle, parallel to the two preceding, and a line and a half from the second, is to be introduced through the sound skin, and all these are pushed on below the presumed thickness of the tumour, and pierce the opposite side also through the sound skin at the same distance from the tumour as they had been first introduced. Secondly, a knot of ligature is put round the first needle, and the end made to go round the opposite point of the second, from that to the

opposite end of the third, and so on, back again, so as to make a regular twisted suture. Thirdly, the end of the ligature being secured by a knot, the ends of the needles are to be cut off as close as possible to the ligatures. The number of needles employed are of course to be in proportion to the size of the tumour, so as to include the whole extent of the disease. Immediately that the threads are tightened, the colour of the tumour disappears, and the swelling is effaced. If we withdraw the needles on the fourth day, there remains at the place which the swelling occupied only a slight bluish white spot, and the skin appearing a little hardened; if the needles are not disturbed until the sixth day, the whole tumour is detached, and leaves behind a linear cicatrix. The essential conditions of the operation are—first, that the needles are passed through the *sound* skin round the affected spot, for if this be not done there will remain a vascular areola, the actual circumference of the original tumour, which is extremely difficult to cure; secondly, that the course of the needles should be through the sound tissues below the presumed thickness of the tumour, otherwise when the swelling comes away, the bottom of the place it occupied will sometimes have a brownish-red colour, with furrows corresponding to the places which the needles had occupied, and when this occurs the return of the disease may be apprehended; third, it is necessary that the constriction of the ligatures should be considerable, but progressive, so as to expel all the blood from the vascular sponge of which the tumour is composed.—*Journ. de Méd.*

TREATMENT OF INDOLENT ULCERS BY ELECTRICITY.

Mr. Bransby Cooper, in his lectures, (*Medical Gazette,*) mentions the advantages to be derived from Grapengiesser's mode of applying a stream of negative electricity, as suggested by Dr. Golding Bird. It is as follows:—

At a convenient distance from the original ulcer, not less than five or six inches, a vesication the size of a half-a-crown is made. The cuticle is detached and on the exposed cutis a piece of zinc-foil is placed of the size of the denuded spot. A plate of silver-foil is laid on the original ulcer, and the two plates are connected by means of a thin copper wire. Both plates are then covered with moistened lint and oiled silk. In a few hours the surface beneath the zinc becomes white and a slough forms. In the meantime a great change has taken place in the original ulcer; it has thrown aside its indolence; new skin forms at the margin, and granulations arise. The rationale of the process is, that the water and chloride of sodium existing in the tissues are decomposed, resulting in the evolution of chlorine, hydrogen and soda. The chlorine uniting with the zinc, forms the well known escharotic, chloride of zinc.

[It is not necessary to take into consideration the electrical action of the above process in explaining the healing of the original ulcer. M. Bresciano (*Half-Yearly Abstract*, vol v. p. 227,) is in the habit of healing old ulcers upon the same principle, by establishing one or more new sores in the vicinity, by caustic potass. He has thus cured ulcers of several years' standing.]

FISTULA IN ANO.

Dr. Van Camp has communicated to the Society of Medicine of Anvers, a method of curing fistula in ano without operation, by means of injections of iodine. A workman, aged 24, had had an enormous abscess at the anus, which became fistulous, its inner opening being very high up in the gut. Wishing to avoid operating in the case, a solution of nitrate of silver was tried as an injection, but it failed to do any service, and recourse was then had to an injection of equal parts of tincture of iodine and water, which was thrown into the fistulous cavity twice a day for five days. The first injections were attended with severe pain, and when the inflammation produced by it was considered sufficient, the proceedings were suspended for three days; they were then renewed, as a little fæcal matter was discharged from the wound, but the cavity had diminished to an inch in height, and by the sixteenth day the cure was complete.—*Jour. de Méd.*

STRANGULATED HERNIA.

The following method for promoting the reduction of strangulated hernia, has been described by Mr. Allen, and will be found in some respects confirmatory of the observations on the same subject, published in a late number of this Journal. Mr. Allen says:—

"What appears to me to be indicated, without entering into all the modifying circumstances, is to adopt such measures as tend to equalize the circulation, contract the vessels, and thus lessen the tumefaction, besides moderating other aggravating conditions, as inflammation, &c., and so apply your means to specific objects. Before the taxis is much tried an attempt should be made to correct the faulty circulation; and if inflammation be present, it should be subdued before much force is employed to lessen the tumour, and overcome the resistance. Now, in addition to what has proved beneficial, I would suggest a plan which I deem highly useful, as in the worst cases I have seen it succeed. It is this: when the strangulation is such as to resist the efforts of the patient and a moderate attempt by the taxis, cautiously to apply to the part fomentations, at about the temperature of the surface, the degree of heat to be progressively increased as high as the patient can tolerate, then to be gradually reduced until the applications are quite cold, which should be persevered in for half an hour, or even an hour. If the hernial tumour is not sufficiently reduced in volume so as easily to be returned, the parts must be again submitted to the same gradual exaltation and depression of temperature, the transitions from one extreme to another being so progressive that the patient is hardly sensible of each immediate alteration: the time from one extreme to the other should not be less than an hour. This plan produces an astonishing reduction in the volume of the hernia when all others have failed."—*Medical Gazette.*

HERNIA OCCURRING THROUGH A LACERATION IN THE FUNDUS UTERI.

Among the "curiosities" of hernia may be mentioned the following, reported by M. Chaptois:—The subject

was a woman, aged 60, who had been long affected with vaginal hernia, which had for some time given her but little inconvenience. As the hernia increased in volume, the dragging sensations, dysuria, &c., were so increased that she could scarcely stand upright. Under these circumstances M. Chaptois was called to her, and discovered that a large quantity of small intestine, together with a portion of colon, had passed through a rent in the fundus uteri, which was completely inverted, and depending from the vulva. After washing the parts, M. Chaptois returned the bowels, and replaced the uterus, still inverted within the vagina, and confined it in situ with a suitable apparatus. Although the symptoms of strangulation had been severe, the patient recovered.—*Gazette Médicale*, No. 51, 1847.

SELF-SUPPORTING DISPENSARIES.

Meeting at Burton-on-Trent.

At a public meeting held in the Town-hall, Burton-on-Trent, January 5th, 1848, the Rev. Samuel Stead, Vicar, in the chair, the Rev. Chairman introduced to the meeting H. S. Smith, Esq., M.R.C.S., of Southam, as having seventeen years previously introduced into the town the "*Self-supporting Dispensary*," which had worked so satisfactorily, and proved so beneficial, to the working classes.

Mr. Smith entered upon the subject of mutual Associations, as the best means of meeting the possibly impending plague of cholera, and elucidated his subject by reference to ancient and modern history. The able and interesting discourse was listened to with the most marked attention by a very crowded and respectable auditory, after which,—

1st.—It was moved by William Daniel, Esq., and seconded by the Rev. R. Greer:—

"That in the event of cholera appearing in the kingdom, the machinery of the '*Self-supporting Dispensary*,' which has worked so efficiently, be made immediately available to meet the emergency, in such a manner as the Committee of that Institution may think most desirable."

2nd.—It was moved by the Rev. W. Morgan, seconded by Thomas Fosbroke Salt, Esq.:—

"That, of the many means of improving the condition of the working classes, there appears to be none that exceed in practical usefulness 'the providing' them with medical attendance in '*sickness by their own small payments*;' and the free members of this Dispensary will assist and co-operate with Mr. Smith, in extending a knowledge of a plan that has been so useful at Burton."

3rd.—It was moved by Robert Sherrat Tomlinson, Esq., M.R.C.S., and seconded by the Rev. T. F. MacMichael:—

"That *due care* being exercised that no improper persons be permitted to enter the Institution, there are no other means by which payments for drugs and attendance can be procured from the industrious with so much advantage as the '*Self-supporting Dispensary*,' which in many instances prevents them from incurring debt,—from going to the parish-doctor,—from quacking themselves,—or from begging *tickets for a charity which they can support themselves*."

4th.—It was moved by Robert Thornewill, Esq., and seconded by the Rev. H. Yate:—

"That the proceedings of this meeting be published in the *Provincial Medical and Surgical Journal*, and a copy of the same be forwarded to the Secretaries of the Provident Dispensaries, at Coventry, Northampton, and Birmingham, and the *Self-supporting Dispensaries* at Grantham and Derby, or such others as may be acting on the principle of self-support."

Mr. Tomlinson, in moving the third resolution, entered fully into a description as to the relative proportions of benefit and injury the self-supporting dispensaries were likely to cause to the medical profession, shewing that the benefits far exceeded other institutions for general adoption.

Mr. Thornewill appended to the fourth resolution a vote of thanks to Mr. Smith, for the great and substantial benefit he had conferred on the town by the establishment of the Dispensary, as well as his kind and instructive lecture; this was unanimously and cordially responded to by the meeting, and the whole proceedings of the evening passed off most satisfactorily.

CONFERENCE OF POOR-LAW MEDICAL OFFICERS WITH THE ROYAL COLLEGE OF PHYSICIANS.

The College authorities having fixed Tuesday, January the 25th, for receiving a Deputation from the Committee appointed by the Convention of Poor-Law Medical Officers, the Deputation, consisting of Dr. Hodgkin, Mr. Vallance, Mr. Peter Martin, Dr. Barnett, Mr. Lord, and Mr. Healey, the Honorary Secretary, met at the College of Physicians, and were received by Dr. Paris, the President, Drs. Clendinning, Todd, Sutherland, and Hawkins, the Registrar.

Dr. Hodgkin, in introducing the Deputation, remarked generally on the objects sought by the Convention, and the manner, (temperate but firm,) in which the Committee desired to carry out those objects. He dwelt on the claims which the profession had when aggrieved, to the assistance of its seniors, and especially of a corporation exercising privately by its members, as well as publicly by its legal position, so much influence as the College of Physicians. The Deputation, in seeking that conference, had it in view to secure the advantage of the College's assistance, and he expressed his hope and confidence as one of its Licentiates, that that assistance would be cheerfully accorded.

The President here remarked that the College did feel a warm interest in the subject which the Deputation was submitting to it, and that in the parliamentary committees under Lord Ashley, he had himself given evidence in favour of a great improvement.

The Deputation then submitted in detail to the President and Censors the different grievances under which

the Poor-Law Medical Officers suffered throughout the country, particularly adverting to the inequality of payment,—its inadequacy,—the short tenure of many Poor-Law Medical Appointments,—the system adopted in giving orders, and the mischief which from all these causes constantly arose to the pauper sick. They referred to instances in illustration, and adverting to the influence the position of the College necessarily gave it with the government, urged on it, that by representations to the government on the one hand, and by joining on the other, (through the President,) a Deputation to Sir George Grey and Mr. Buller, to be sent from the Committee, the College would exercise all its power to mitigate an evil alike mischievous and dishonouring to the whole profession.

The President and Censors having promised to give their best consideration to the statements of the Deputation, expressed the warm interest they felt in removing the grievances complained of, with an assurance that the College would be glad on every occasion to communicate with the Committee, and to second, as far as practicable, their exertions.

The Deputation having expressed their acknowledgements for the marked courtesy and cordiality with which they had been received, and their representations heard, then retired.

AGE OF PUBERTY IN ENGLAND: MR. WHITEHEAD AND MR. ROBERTON.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I shall feel greatly obliged if you will allow me, through the medium of your next publication, to correct an error which I inadvertently committed in my letter inserted in the *Provincial Medical and Surgical Journal* of last week. I may just be permitted to remind your readers that the object of the letter in question was to rectify two statements, presently to be repeated, which appear in my work "On Abortion, Sterility, &c.," regarding Mr. Roberton's researches on the age of puberty, conducted among the patients of the Manchester Lying-in Hospital.

Relying upon an imperfect recollection of my former reading, and not having at the time an opportunity of again consulting the necessary documents, I stated in my letter that the conclusions at which Mr. Roberton had arrived respecting the age of puberty in this country,—namely, that the average age of female puberty was, for England, fourteen years and ten months; and that the proportion of instances in which puberty was developed before the age of eleven years, was 3.15 per cent., as stated in his paper published in the *Edinburgh Medical and Surgical Journal*, vol. 66,—were deducted from a table comprising the result of his own inquiries and those of Professor Murphy, inserted in the 26th volume of the *Dublin Journal of Medical Science*; and that the inquiries of the latter were made among the Irish. On referring to the paper in question, I found, at a period, however, when it was too late to correct the errors in my last communication, that Professor Murphy's table was, on the contrary, compiled from his own investigations and those of Dr. Robert Lee, both made in London, including also the inquiries of Mr. Roberton, instituted at Manchester.

The following statement exhibits the results of Mr. Roberton's and my own investigations respectively, as they ought to have stood in my treatise:—

Average age of puberty for England, according to Mr. Roberton's table . 15 years and 3¾ mths.
The result of my own inquiries 15 years and 7 mths.

Proportion of instances arriving at puberty before the age of 11 years, according to Mr. Roberton 2.22 per ct.
The result of my own inquiries . . 0.225 „

That the above-mentioned errors have occurred, is a circumstance that I much regret. And should they have caused some degree of pain to the gentleman referred to, Mr. Roberton, (as I am privately informed has been the case), the explanation now given will, I trust, entirely satisfy him that nothing was farther from my thoughts than to misrepresent any of his views and statements.

I am, Sir,
Yours very respectfully,
J. WHITEHEAD.

Manchester, Jan. 31, 1848.

Medical Intelligence.

MORTALITY OF MEDICAL PRACTITIONERS IN IRELAND FROM FEVER.

It is with deep regret that we notice the ravages which fever continues to make in the ranks of our medical brethren, in Ireland. Scarcely a week passes without the loss of three or four district medical officers from this cause being announced in the *Dublin Medical Press*. During the late epidemic, of twenty-seven physicians attached to fever hospitals and districts in the province of Ulster, attacked with fever in the discharge of their duties, fourteen, or more than half, died, leaving nine widows and thirty-seven children, for the most part but scantily or not at all provided for. These gentlemen have fallen a sacrifice in the faithful discharge of duties entrusted to them by the public, in the endeavour to restore health to the sick, and administer assistance to the dying; surely their families are at least as much entitled to a provision at the hands of the government, as those of any other class of public servants.

DEATH FROM THE USE OF CHLOROFORM.

We regret to state that a case has occurred in which death was apparently owing to the employment of the vapour of chloroform. The operation was that of removing the toe-nail, and about a drachm of the chloroform was used to induce insensibility; the patient was a girl of fifteen, much reduced in her general health, who had undergone the same operation at the

Newcastle-upon-Tyne Infirmary, in which chloroform was also employed, about four months ago. The fatal event took place about three minutes from the first inhalation of the chloroform, the nail having been removed in the interval. An inquest was held, and the immediate cause of death was stated by Sir John Fife and Dr. Glover to have been congestion of the lungs. The verdict of the jury was, "that the deceased, Hannah Greener, died from congestion of the lungs, from the effect of chloroform, and that no blame can be attached to Mr. Meggison, surgeon, or to his assistant, Mr. Lloyd."

APPOINTMENTS.

William Thomson Barker, M.D., has been elected one of the Physicians to the Dumfries and Galloway Royal Infirmary, in the room of Dr. Robert M'Lellan, deceased.

Campbell De Morgan, Esq., F.R.C.S., has been appointed Surgeon to the Middlesex Hospital, in the room of Mr. Tuson, resigned; and Charles Hewitt Moore, Esq., has been elected Assistant-Surgeon, in the room of Mr. De Morgan.

James Dixon, Esq., F.R.C.S., Surgeon to the London Ophthalmic Hospital, has been appointed Assistant-Surgeon to St. Thomas's Hospital, in the room of Mr. B. Travers, jun., resigned.

The appointment of Dr. Meyer as Physician to H. R. H. Prince Albert, mentioned in the last number, is, we have authority in stating, an error. Dr. Meyer is not a Physician, but a Doctor of Philosophy, and has been for some years attached to the establishment of Prince Albert as Librarian.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted members on Monday, February the 28th:—J. Jordan, N. Marsh, H. Armstrong, R. Gorst, P. Y. Gowland, J. T. Jackson, H. Dermott, T. J. Sayer, A. Goodchild.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, January 20th, 1848.—James Bailey, Wednesbury; George Robart Hanbury, Hereford; Frederick Greenwood, Huddersfield; John Broadbent, Leeds; Josiah Clarkson, Birmingham.

Gentlemen admitted Licentiates, Thursday, January 27th:—Henry Christmas Walton, Liverpool; John James, St. Just, Penzance; Thomas Wise, Malton; George Reynolds Schofield, Leeds; James Rice; George Fry, Mayfield, Sussex.

OBITUARY.

Died, January 1st, at Fintona, of fever, Andrew Allen, Esq., late Surgeon, Royal Navy.

January 6th, at Kendal, aged 79, Edmund Tatham, Esq., Surgeon.

January 7th, William Finch, M.D., F.L.S., Physician to the Laverstock Lunatic Asylum, Salisbury.

January 9th, of fever, Samuel Edward Barnes, Esq., Surgeon to the Ballymore Eustace Dispensary.

January 11th, at Kilrea, aged 34, of fever, John Chaine Hunter, Esq., Surgeon to the Tamlaght Dispensary.

January 16th, at Baldock, aged 40, Robert Inverarity, Esq., Surgeon. Mr. Inverarity had scratched one of his fingers, and afterwards dressed the arm of a patient affected with phlegmonous erysipelas. Shivering occurred the following afternoon, diffuse inflammation of the cellule texture supervened, and he died on the eighth day from the attack.

January 23rd, of fever, Charles Hyndman, Esq., M.B., Physician to the Sick-Poor Institution, Meath Street, Dublin.

January 25th, at Edinburgh, J. W. Reid, M.D., Surgeon, R.N.

January 27th, of fever, Richard Strong Sargent, M.D., Physician to the North Dublin Union Fever-Sheds.

January 29th, at Edinburgh, of fever, Joseph Bell, M.D.

January 31st, at Sevenoaks, aged 51, James Gellatly, M.D.

Lately, George Leopold Perfect, M.D., Town Malling, Kent.

By J. Y. Simpson, M.D.,
Professor of Midwifery in the University of Edinburgh.

Sect. V.—Relative Periods of the Labour at which the Long Forceps, Perforation, and Turning, are respectively employed: Value of Auscultation in Operative Deliveries.

In the preceding section I have attempted to shew the comparative advantage of turning over the employment of the long forceps or crotchet, on the ground that we could thus accomplish the delivery much earlier in the course of the labour, and hence much more safely for the mother. In fact when the long forceps are used in instances of arrestment of the head at the brim, they are in general never applied till the cranium is thrust and wedged down into the upper pelvic aperture to as great an extent as can possibly be effected by the unassisted uterine efforts, and till symptoms of local irritation, or constitutional re-action or exhaustion offer to appear. But before all this state of matters is brought about, both much expenditure of muscular and vital exertion on the part of the mother, and also much expenditure of time is usually required; and the walls of the maternal passages are liable to have become injured by irritation and compression. Before the assigned conditions are produced, many long hours commonly elapse, each one of them directly and rapidly adding to the chances of danger to the mother. On the other hand, in the same set of cases, if artificial delivery by turning were adopted, it might and would be practiced as early as the passages were adequately dilated, before the head were pushed down into the pelvic brim, and long before any symptoms of local lesion or general irritation and exhaustion presented themselves.

But it is principally as a substitute for craniotomy that I venture to suggest the operation of turning in instances of arrestment of the head at or above the brim of the pelvis. And when we contrast the different times as far as regards the duration of labour, at which these two modes of delivery (craniotomy and turning,) would be respectively followed in the same class of cases, we shall perceive still more strongly the advantages of the alternative practice. For turning, as I have just now stated, would necessarily be performed early in the course of the labour, and so far at a period when the danger would be comparatively slight, according to the law of duration which I have attempted to establish. Commit, however, the same morbid cases to the usual rules of management, by which they would be treated under the prospective idea that they would in all probability ultimately become cases of craniotomy, and mark the difference. The labour is allowed to go on from hour to hour, and possibly for one or two long and weary days, in order to give the child every legitimate chance of being, at last, expelled alive, or, at least, expelled without operative mutilation. In the meantime, however, as the preceding tables abundantly prove, the chance of immediate or ultimate danger to both mother and infant increases fearfully in proportion as the labour drags on its duration. How long then shall we allow it to continue before we perforate and break up the child's head? Most modern authorities would answer that question by earnestly inculcating the propriety of not applying the perforator till the child were distinctly and certainly dead, (unless indeed the appearances of danger to the mother were extremely marked and imminent,) for almost all eagerly and properly declare their abhorrence at the idea of "plunging an iron instrument into the centre of the skull of a living human being."

But how long must we probably wait before the child really dies? We have seen, (Table III.,) that the infantile, like the maternal, mortality increases in a ratio progressive with the increased length of the labour; and that out of all cases in which, in the Dublin Hospital, the process of parturition was prolonged beyond thirty-six hours, one in every two of the children was lost. But still the labour may go on to the fortieth, fiftieth, or sixtieth hour, and yet the child live. Out of twenty-seven cases in all, reported by Dr. Collins, in which the labour was prolonged to sixty hours and upwards, in sixteen the child was ultimately born dead; and in the remaining eleven it seems to have still survived and ultimately to have been expelled

* Continued from page 60.

alive. Whilst, however, we are thus waiting and watching for the certainty of the child's death *before* we operate, the chance of the mother's death increases with the lapse of every hour. Out of these same twenty-seven cases of labour prolonged sixty hours or upwards, seven of the mothers, or one in every four, perished. We may thus wait with the expectation of the infant's death, till at last we run the imminent hazard of also losing the mother; and even then, when at last we find ourselves driven to have recourse to craniotomy in order not to place the parent in greater jeopardy, we may be unwillingly compelled to practice the operation while the child still really lives, goaded on by a dire but now irresistible necessity to attempt to save the life of the mother by taking away the life of her child.

Auscultation is the criterion upon which all modern accoucheurs properly and mainly depend for ascertaining the death of the infant, and fixing the date at which it threatens to perish, or actually does perish, during a protracted labour. And certainly, in the progress of a prolonged case, auscultation is, as Dr. Collins states, of "immense value in ascertaining the life or death of the child." "I know (he remarks,) of no case where the advantage derived from the use of the stethoscope is more fully demonstrated than in the information it enables us to arrive at with regard to the life or death of the fœtus, in the progress of tedious and difficult labours. It is, in my opinion, one of the greatest improvements made in the practice of midwifery."* The whole evidence of Dr. Collins' general remarks and individual cases shews, that in protracted parturition the special advantage which he has found, and expects others to find, from the employment of auscultation, is a far more precise and certain knowledge than we could otherwise possess, of the life or death of the infant, and of the exact time at which it does die, with a view of fixing more exactly the time at which we should deliver it by craniotomy. Actuated by the best and most humane feelings, Dr. Collins believes that in tedious and difficult labours obstetricians should rarely or never perform craniotomy upon the head of a *living* child, and that auscultation will enable us to eschew this otherwise unavoidable error. For, in one set of cases, it will shew us the propriety of postponing the operation, by shewing us that the child's heart is still beating. In another set of cases it will shew us the propriety of practising it earlier than we would otherwise do, by shewing us that the child is already dead. At the same time we must still not use our perforator immediately after the fœtal heart ceases to be heard by the stethoscope, or indeed for some hours afterwards, lest life be not perfectly and entirely extinct in the child. "It is totally contrary (says Dr. Collins,†) to every rule of practice, to deliver the patient with the crotchet when the fœtal heart's action *first* becomes inaudible. It is only after frequent examinations, with some interval between each, that this is ever resorted to, except where the mother's life is in *very imminent danger* indeed."

Such is the use and value of auscultation in protracted labours, according to the opinion of Dr. Collins and of the Dublin school generally; and certainly, while for one, I most gladly and gratefully acknowledge that it is to that school that British midwifery stands indebted for the first introduction of auscultation into English obstetric practice, still I cannot help declaring my conscientious conviction here, as I have often done in lecturing upon the subject, that the preceding application of it in tedious labours is so far undoubtedly erroneous in two most important and fundamental points.

For, *first*, according to the principles upon which the Dublin practitioners use auscultation in tedious labour,—viz., in order to fix the fact of the death or life of the child, with a view to the immediate performance or future postponement of craniotomy, they altogether leave out of consideration the great influence which the mere duration of the labour exerts upon the maternal constitution and life. They forget that whilst they are delaying for the death of the child, the very delay is rapidly destroying the mother;—whilst they are waiting and watching for the fœtal life becoming extinct, the maternal life is every hour becoming placed in greater and greater danger. Under proper management, argues Dr. Collins, the death of the child takes place in laborious and difficult labours, before the symptoms become so alarming as to cause any experienced physician to open its head for the sake of the safety of the mother. But I believe his own facts totally and sternly contradict this argument. When for this or other causes he waited till the labour had continued from twenty-five to thirty-six hours from its first commencement, one in every seventeen of the mothers died; (see Table No. II.;) when he waited for twelve hours longer, allowing the labour to be prolonged from thirty-seven to forty-eight hours, then one in every six of the mothers was lost; when he waited for twelve more hours, (namely, forty-nine to sixty hours,) then one in every five of the mothers was lost; and when intereference was not adopted, or delivery completed, till the labour had gone on for sixty hours or upwards, then one in every four of the mothers perished; and that too, although, as we have already seen, in eleven out of twenty-seven cases, or in about one in two-and-a-half of these very same protracted labours, the child was still living, and was indeed ultimately expelled alive, thus *still* contra-indicating craniotomy, as far as its life was concerned, notwithstanding that the life of the mother was reduced to such an extreme degree of danger and hazard.

But, *secondly*, the opinions which Dr. Collins and

* Practical Treatise, p. 18.

† *Dublin Medical Journal*, Vol. xiii., 1838, p. 423.

others of the Dublin school profess with regard to the application of auscultation as a valuable aid to the management of tedious and instrumental labours are, I conceive, still more objectionable in another point of view. In cases of protracted parturition they use the stethoscope, as we have shewn, in order to ascertain the life or death of the child, and in order to decide and determine the proper time at which embryotomy should be performed. For this purpose they employ it with the special object of fixing the fact that the child is dead; and fixing, when requisite, the true time when it does die. But I am strongly of opinion that the mighty boon which auscultation offers us in protracted parturition is quite different, and far more important. For it is not by any means so valuable in thus often affording us evidence that the child is dead; it is not so much of real and practical use in shewing us that we may now perform embryotomy upon a dead infant, as in shewing us *when*, in protracted cases, we ought to extract the child by the forceps or other safe means, if we wish to *preserve* its life, as well as the life of the mother. In this way I have repeatedly found auscultation of incalculable benefit in protracted labours, and been, I believe, enabled by its evidence alone to save several times the life of the child by the timely application of the long and short forceps. And though the principle upon which I have thus acted in the management of tedious labours is not acknowledged by Dr. Collins under that subject, yet, certainly, the very same principle of using instrumental delivery for the sake of the safety of the child is acknowledged by him under another head, and in dependance upon another form of evidence of the danger of the infant. In speaking of the treatment of cases of prolapsus of the umbilical cord he observes:*—"The forceps I consider highly desirable when the child is so situated that the head can be reached with safety; but as the funis generally descends at the commencement of labour, it is very seldom that this instrument is applicable till fœtal life is extinct. We shonld not fail, however, to apply them when practicable, should any delay occur in the delivery likely to *endanger* the life of the child, or if we find *the pulsation in the cord becoming gradually slower and more feeble.*" Now, exactly on the same principle, when in tedious labours in which there is no contra-indication, we have evidence that the life of the child is becoming endangered, when by the stethoscope we learn that the pulsations in the fœtal heart are becoming gradually slower and more feeble, it is in my opinion equally our bounden and solemn duty to interfere by the same means in order to attain the same end, viz., the preservation of the infant's life. For I hold that neither in principle nor in practice does it make any difference whether with this view we ascertain the imminent danger of the child, and the fact that the pulsations of its heart are becoming slower and more feeble, by *feeling* the pulsations of the cord, or by *listening* to the pulsations of the heart itself. The sense of hearing affords us precisely the same evidence in the one case as the sense of touch affords us in the other, and it indicates also precisely the same line of treatment.

The bearing of this long discussion and digression upon the practice of turning in contracted pelves, &c., is sufficiently evident. Over both the operations for which I propose it as a substitute,—viz., delivery by the long forceps and crotchet, it possesses this great and weighty advantage, that it can be practised at a far earlier, and consequently at a far safer, period of the labour. But it is principally as an alternative for craniotomy that I feel anxious to introduce the operation of turning to the consideration of my professional brethren; and over craniotomy it possesses, in addition to the above, this other all-important advantage, that it offers the child a chance of life, while craniotomy implies the very certainty of death; and that while the existence of the sounds of the fœtal heart, and the continuance of the infant's life, would determine us to postpone, and postpone almost indefinitely, the delivery by embryulcio, the existence of these sounds, and the evidence they give of the continuance of the infant's life, would determine us to adopt, and form indeed, *cæteris paribus*, the very strongest reason for adopting delivery by turning. In the one operation we would delay, and perhaps delay long, and hence dangerously, the delivery of the mother, because the child was living; in the other operation we would promote and hasten the delivery of the mother on exactly the same grounds on which we postponed it in the first,—viz., because the infant was still living, and might still be extracted alive.

Perhaps the detail of one or two cases may impress this view more strongly than any more lengthened remarks. I shall select the two first from the Clinical Report of Dr. Lee, of London, who, like Dr. Collins, rejects the employment of the long forceps when the head is delayed at the brim, and prefers the extraction of it by the perforator and crotchet.

Case IX.—In a woman whose pelvis and extremities were distorted by rickets the labour began on the 9th of February, 1842.† "The membranes," to quote Dr. Lee's own words, "ruptured on the 10th. On the 11th, the os uteri was not dilated to the size of half a crown, the head was wholly above the brim, and the base of the sacrum easily felt. Active pains came on and lasted during the night, and till two p.m. of the 12th. The os uteri was still very imperfectly dilated. The head *entirely* above the brim now much swollen. It was clearly right to interfere, which I did, (by craniotomy,) and she recovered without a bad symptom, though I now feel persuaded that she ought *not* to have been left so long in labour. The danger (he adds,) of rupture and fatal contusion of the uterus is great in

* Practical Treatise, p. 344.

† Clinical Midwifery, Case 113, p. 51.

all such cases and delivery should be effected as soon as it is evident that the head cannot pass. I knew from the first, in this case, that it would not pass through the brim, but was *prevented from interfering in consequence of hearing the pulsations of the fœtal heart.*"

In the preceding case Dr. Lee states his conviction that the patient ought not in reference to her own safety, to have been left so long in labour. The continuance, however, of the pulsations of the fœtal heart prevented him for some time, from interfering and delivering by craniotomy. It is not stated whether the child continued alive or not when that operation was at last adopted. But the circumstance which thus directly deterred him from earlier delivery, viz., the life of the fœtus, would have directly urged him to the new practice which I am here venturing to propose in such cases. The reason he had for longer postponing the operation of craniotomy, would have been the strongest of all reasons for at once preferring the operation of turning, and giving so far, a chance of life to the child, and at the same time preventing the continued duration of the labour, from placing the mother in greater danger and jeopardy.

I quote the following case from the same author for the purpose of shewing, what I have omitted to insist upon in the course of the preceding remarks, that in instances in which the brim of the pelvis is contracted, the protracted duration of the labour may occasionally lead to the most deplorable morbid consequences on the part of the mother, even though it do not actually destroy her life. An earlier delivery by turning would, I believe, as has been already often stated, not only enable us to avoid these results to the mother, but offer a chance of escape and life to the child.

Case X.—The patient* had borne nine children; all her labours had been difficult, and the two last so much so that artificial assistance was required, and the children were still-born. Her tenth labour commenced on the 3rd of December, and the membranes were soon after ruptured. During the 4th the pains were feeble and irregular. Thirty-five drops of laudanum were given. On the morning of the 5th they returned, but again feebly and irregularly. At ten o'clock of the evening of the 5th two doses of the ergot were given, and soon several strong forcing pains were experienced. "The movements of the infant were not felt after this," and the uterine contractions appear to have ceased. When Dr. Lee visited her next forenoon,—viz., at eleven o'clock on the morning of the 6th, (three days after the labour had commenced, and the membranes had been ruptured,) the state of the patient was as follows:—"The discharge from the parts has become offensive; bladder filled with water; the vagina is swollen and tender; the head greatly swelled and compressed, is firmly fixed in the brim of the pelvis, and the finger cannot be passed around it without giving great pain; the ear cannot be felt, the greater portion of the head being still *above* the brim." Dr. Lee opened the head, and two hours elapsed before he could complete its extraction with the crotchet. He thus continues the report:—"December 7th. A bad night; retention of urine; great swelling and tenderness of the parts; pulse rapid; tongue loaded; headache; rigors. Sloughing of the vagina took place, and on the 14th a *fistulous* communication had been formed between it and the bladder. This unfortunate woman (adds Dr. Lee,) was soon after deserted by her husband, and has led a life of great indigence and misery ever since."

In offering some general concluding remarks upon this and sixty-five other cases* of "difficult labour from distortion of the pelvis, &c., &c., in which delivery was effected by the operation of craniotomy," contained in his second report, Dr. Lee observes,—"In thirty-eight of the cases in this report, the labour continued from forty to seventy hours."—"In a very large proportion of the cases the difficulty arose from distortion, or a contracted state of the pelvis. Rupture of the uterus took place in three before perforation, and the inflammation and sloughing of the uterus, vagina, and rectum, which proved fatal to eight others, were chiefly or solely produced by the long-continued violent pressure on the soft parts by the head of the child *before* it was opened and extracted. In those who recovered with vesico-vaginal fistulæ or contractions of the vagina from cicatrices, the unfortunate occurrences arose from craniotomy being too long delayed."—"In several, had the delivery been *sooner* effected, the fatal consequences which ensued would have been wholly prevented."

In some of the following cases from Dr. Collins' report, the delivery of the patients by craniotomy was evidently postponed till such time as the child was ascertained by the stethoscope to have died. The state of the fœtal heart is not mentioned by Dr. Collins in all, but the omission was probably made in order to avoid unnecessary repetition; and except for this counter-indicating circumstance (the continuance of fœtal life,) the mothers would probably not have been allowed to have their sufferings protracted, or so much constitutional excitement created, before resorting to artificial delivery. In the last or last two cases, the state of the mother probably ultimately necessitated delivery, independently of any considerations relative to the life of the infant. I shall quote the cases in Dr. Collins' own words.

Case XI.—"Was admitted in labour of her eleventh child; uterine action very frequent and strong; the os uteri dilated to the size of a crown, and the fundus very much inclined to the right side. In twenty-four hours after admission, (the head not having made any progress for the last eight,) *the fœtal heart having ceased to act for some time*, it was thought advisable to lessen the head, and deliver with the crotchet."†

* Clinical Midwifery, Case 84, p. 40.

* Clinical Midwifery, p. 59.

† Collins's Pract. Treatise on Midwifery, p. 480, No. 1032.

Case XII.—"Was admitted in labour of her seventh child; she had been delivered artificially in her previous labours, and had but one child born alive. She had been ill a considerable time before she was brought to the hospital, and in nine hours afterwards, there being no progress made, the pulse 132, her strength much exhausted, and the child *dead*, she was delivered by the crotchet."*

Case XIII.—"This patient was admitted in labour of her first child; uterine action was feeble, and continued so for seventy-two hours after she came in. As the *fœtal heart had ceased to act for some time*, and the pulse became hurried, it was considered advisable to deliver her. The *os uteri was not fully dilated;* the head was *high*, and resting on the pubes; it was lessened, and cautiously brought down with the crotchet."†

Case XIV.—"Was reported to have been in labour two days before admission; the head was high in the pelvis, and pressing strongly on the pubes. It remained in this situation for twenty-four hours after, during which time she suffered great distress, uterine action being almost constant. This was her tenth child; she had been twice force-delivered in this hospital; dreading every moment rupture of the uterus, the head was lessened and brought down by the crotchet, as it had still remained so high as to be scarcely within reach of the finger."‡

Case XV.—"Was reported to have been twenty-four hours in labour before admission. About twelve hours after she came in, it was discovered that the face was turned towards the pubes, and pressing so strongly on the urethra the catheter could with difficulty be passed. The pains continued strong for fifteen hours from this time, yet the head did not advance. It was deemed advisable to lessen it."§

Case XVI.—"Was thirty-three hours in labour of her third child without having made the least progress for the last twelve. The bladder was forced down before the head. Her pulse became much hurried, and strength greatly exhausted, rendering immediate delivery necessary. The head was lessened, and the child brought away by the crotchet. It was very large; all her former children were still-born."‖

Case XVII.—"S. B. was forty hours in labour; it was her fourth child; all still-born. The head not having made any progress for the last twelve hours, and the fœtal heart having ceased to act, the delivery was effected with the crotchet; the face was turned towards the pubes. She had been force-delivered in this hospital two years ago, when the face presented; (see 'Observations on Still-born Children,' No. 441;) pelvis very defective. The placenta in the present instance had to be removed by the hand, in consequence of hæmorrhage; it was firmly adherent to the fundus of the uterus. She died on the ninth day, and on examination, extensive ulceration of the vagina was found, forming a communication with the rectum. At one point the vagina presented the appearance as if a laceration had taken place."*

In these cases delivery by turning, instead of by craniotomy, by being performed earlier, would, I believe, have preserved the patients alike from the sufferings and the dangers which the continued duration of the labour entailed upon them; and the children, instead of being necessarily sacrificed by the operation adopted, and the delay attending upon it, might possibly have been saved by the adoption of turning, and by the earlier period at which delivery could thus have been practised. But it has been doubted whether the object I have just alluded to, namely, the preservation of the infant's life, could ever be the result of forcible extraction of the child through a contracted pelvis by turning. I shall next therefore notice this and other objections to the proposed practice on the allegation of danger to the mother, and disarrangement of the mechanism of parturition. The investigation of the objections urged on these several grounds will, I believe, leave us only with higher and more certain ideas of the real advantage of the proposed practice itself.

SHORT NOTES OF THE OPINIONS AND PRACTICE OF THE LATE JOHN PEARSON ESQ., F.R.S., ON SYPHILITIC DISEASE.*

By W. S. Oke, M.D., Physician to the Royal South Hants Infirmary.

Ulcers on the Tonsils.—Ulcers on the tonsils are generally the first evident proof of the syphilitic poison having entered the system. When the poison has had a silent introduction, the ulcers are longer in appearing; but even in this case the intervening period seldom exceeds four months; and although there are instances where it has not been possible to trace the ulceration of the tonsils to any previous disease, yet it cannot be doubted that it must have been derived from a chancre. A sense of pricking in the act of swallowing usually precedes these ulcers. The ulcer is deep, and penetrates into the substance of the part; the surface is irregular, and is covered by a whitish slough; the gland is seldom much enlarged, and has a dark red circle surrounding the sore, which is most painful at night. These ulcers do not prevent deglutition, but they sensibly affect the voice, obstruct the hearing, and cause a disagreeable taste in the mouth. The ulceration does not proceed rapidly, even when mercury is not employed. The tonsils are more frequently affected than the soft palate, its arches, or the uvula, and these are not always affected by the spreading of the ulcers from the tonsils.

* Continued from page 34.

When the whitish slough has been removed by the use of mercury, the surface of the ulcer will look as if it had been scraped, an appearance seldom seen in sores that are not syphilitic, and in which mercury of course has not been used.

The virus often attacks the posterior part of the fauces, which becomes sloughy, and discharges a thick matter of a greenish colour. The epiglottis is seldom destroyed, though often ulcerated; and when the larynx is involved, the disease generally proves fatal. In this case there is a peculiar sound of the voice, a troublesome cough, and frequent retching.

In syphilitic sore-throat the lymphatic glands of the neck are seldom affected; and when they do become enlarged, it is probably from a scrofulous habit of body.

There are four morbid conditions of the throat, which more or less resemble the syphilitic.

1st. Ulcers on the tonsils in scrofulous constitutions, or in women of a delicate and lax habit of body. There is nothing which particularly characterizes this species, except that it cannot be traced to any specific cause, and that it will get well by medicines that improve the general health.

2nd. Specks of ulceration upon various parts of the fauces, resembling lupus, destroying and ulcerating more rapidly than lues, and quite as extensively. The tonsils, uvula, soft palate, larynx, or nose, are sometimes partitally or wholly destroyed, without the slightest proof of any syphilitic origin.

3rd. Cancerous ulceration of the tonsils to a great extent, with enlargement of the glands of the neck.

4th. Ulceration from the adhibition of mercury at an early period of the course. This species puts on an erysipelatous aspect; and as it appears to arise when the antidote is manifesting its curative action upon the disease, the ulceration cannot reasonably be imputed to the advance of the disease itself. But when this condition of the throat has existed two or three weeks, the diagnosis is by no means easy. It commits great ravages, and is attended with pain, erythismus, deafness, and a sallow countenance. These symptoms will, however, generally yield to sarsaparilla, bark, mineral acids, and a generous diet.

Sometimes there will be considerable enlargement and spongy appearance of the tonsils, with slight ulceration; both tonsils being affected generally at the same time. This case is not venereal, but probably arises from a tendency to become ulcerated upon common exciting causes from former syphilitic disease.

Treatment of Venereal Sore-throat.—It was formerly the custom to use mercurial fumigation in all venereal ulcerations of the throat, and it is very useful in speedily arresting the progress of the disease when rapidly destroying important parts, but so many inconveniences attend upon its use, that it is seldom employed in private practice, except in very serious cases. A proper fumigating machine should be procured, and the cinnabar thrown upon hot iron. [Nothing answers better than a *small* tin funnel, inverted over a circular thick plate of iron; the tube must be, of course, sufficiently long, and curved at the extremity with a nozzle.] Half a drachm or a drachm of cinnabar should be used twice daily. The fumes ought not to be drawn into the lungs, as they are apt to excite coughing and uneasiness in the chest; sometimes, indeed, the brain becomes affected by its use, so that it always should be cautiously watched during its operation.

Where the ulcers are foul and sloughy, they may be advantageously treated with equal parts of the muriated tincture of iron and honey of roses, or with the tincture alone. The following gargle also may be employed:—

R. Hydrargyri Bi-chloridi, ... gr. viij;
Acidi Hydrochlorici, ... gtt. xxv;
Decoct. Hordei, ... Octarium. Misce.

It is of great importance that the ulcer should be healed before the mercurial course is discontinued.

Unless a patient with a venereal sore-throat is exposed to the full effect of mercury from six to eight weeks, he will be liable to a relapse.

If the ulcer should become foul or stationary towards the end of the course, not yielding to the applications above recommended, lunar caustic should be applied, or an undiluted mineral acid, for a minute or two, and then washed off with barley water.

When there have been venereal ulcers in the throat, there will be left in the parts a tendency to become ulcerated, on slight occasions, for some years, especially in scrofulous constitutions.

Venereal Eruptions.—These may appear, prior or subsequent to the sore-throat, and they do not observe any regular order; sometimes both occur at the same time.

To a certain extent the tonsils are external parts; they, as well as the surface of the body, are liable to be affected by the atmosphere. The cause of the venereal disease first appearing as a secondary symptom in the throat, is perhaps the similarity of their structure to the surface of the body. The surface of the body is covered by an oily and lubricating secretion, to prevent too great evaporation. The oily matter is secreted by sebaceous glands, and is generally mixed with the sweat. These glands are very numerous about the nose, behind the ears, on the areola of the nipples, on the umbilicus, inside of the thighs, between the scrotum and thighs, on the corona glandis, labia pudendi, &c. They have been found in all the above-named surfaces, and it is probable that no external part is absolutely without them. The venereal poison irritates these glands, and produces a morbid secretion and suppuration in them. Where they are fewest in number, or where the parts are particularly exposed to the air, the eruptions appear sooner, as on the neck and

breast; but where the glands abound, these take place later. Hence exposure to cold air, and cold bathing, seem to accelerate eruptions; whilst sudorifics, warm bathing, &c., retard them.

We seldom meet with eruptions on the arms and thighs of men, because these parts are covered; but in women it is very common to see an eruption on both. It is also unusual to see spots of this kind about the root of the nose, or on the eyelids, or roots of the hair, from these parts being well supplied with moisture from the sebaceous glands.

The tonsils are exposed to the atmosphere, and particularly to a current of air. They are said to be mucous glands, but the matter secreted by them resembles that of the sebaceous glands. When they become ulcerated, a thick and sebaceous discharge is produced, and when they burst they appear filled with this sebaceous substance, which sometimes is so offensive that it is scarcely possible to remain in the room with the patient.

In other diseases of the tonsils, also, the sebaceous matter exhales such an intolerable odour, and so taints the breath, that it sometimes becomes necessary even to extirpate the diseased part. When the secretion is suffered to accumulate about the toes, and in other confined parts, it is well known that the smell becomes very offensive.

Why the syphilitic poison first attacks these sebaceous glands, it is difficult to explain, but it is evident that the first appearance of the disease in its secondary form is always in those glands. The skin is most frequently marked by spots, nearly flat, squamous, copper-coloured, and circumscribed; the diameter is that of a split pea, or a silver penny. They sometimes run together, and form broad patches. They are met with on the neck, breast, inside of the fore-arm, elbow-joint, inside of the thigh, groin, and lower part of the abdomen. In cases of long continuance the eruptions are somewhat different; the spots are circular, of the size of a silver penny, having a little scale in the centre, surrounded by a dark circle, and are chiefly met with on the breast and shoulders. These spots are probably produced by an effusion of blood under the cuticle, obliterating the rete mucosum, and leaving, when cured, a cicatrix of a whitish colour in the centre.

Sometimes the form of the eruption is pustular, appearing on one or more parts of the body, and resembles distinct small-pox, for which it has been occasionally mistaken; but it is less bold and prominent, and there is no redness in the interstices. When the crusts fall off, they leave a dark appearance of the skin, and do not return. They appear first on the face, and then upon the anus, groins, upper part of the thighs, and lower part of the abdomen.

When there is an eruption about the roots of the hair, they are generally small, and have a dark crust on the surface. They do not affect the whole of the scalp, and are usually observed on other parts of the body at the same time. There is also an eruption similar to tubercles, being hard, elevated, of a dusky-red colour, and containing no fluid. This is often seen on the scrotum, labia pudendi, and inside of the thighs. Another kind of venereal eruption resembles stripes, forming circles, and containing a watery fluid. When these burst, crusts form, and falling off, leave large ulcers, which are disposed to produce fungi.

It ought, however, to be borne in mind, that an eruption may appear on the body of a syphilitic patient from other causes, and that it is not justifiable to pronounce the eruption to be venereal, unless from a correct history of the disease we have good reason to believe it to be such, or unless the eruption be combined with some other venereal symptom.

Treatment of Venereal Eruptions.—When a venereal eruption and nodes exist at the same time, and are removed by a course of mercury, if a relapse occur, the eruption will return, proving that a venereal eruption requires more mercury for its cure than nodes, and thus one symptom may return, and not another. Venereal eruptions are seldom cured till six or eight ounces of mercurial ointment have been used. They may dry, and fall off in furfuraceous scales, or dark-coloured crusts may form; but so long as there is any elevation left about the cuticle, this treatment ought not to be discontinued. The surest criterion of the virus being destroyed is (and which should always be looked for,) *a little depresssion with a whitish cicatrix in the middle of the blotch.* This is often very minute, but it may be detected with attention.

The cure of venereal eruptions is facilitated by the prudent use of the hot bath, heated to about 90°; it may be used once or twice a week, for ten or sixteen minutes at a time. The warm bath lessens the effect of mercury, but in what manner it cannot be explained.

It will also sometimes be proper, when there are venereal pains, when the skin is dry, and when the eruption does not fade kindly, to give the compound ipecacuanha powder, or equal parts of antimonial wine and laudanum, at such intervals as may be thought necessary.

Lippitudo syphilitica.—This is an increased morbid secretion of the sebaceous glands of the tarsi of the eyelids. It is not so frequently met with as eruptions, with which it is sometimes conjoined. Lippitudo arising from the venereal virus, does not differ from the ophthalmia tarsi depending on other causes, except that there is a peculiar excoriated appearance of the external angle of the eye, and a loss of substance of the punctum lachrymale, especially when the disease has been of long standing. It sometimes produces a spongy appearance of the conjunctival membrane, and at others a great part of the eyelids will be destroyed. There are no diagnostic marks by which the disease

can be distinguished from common lippitudo; but whenever the external angle of the tarsi is excoriated, and is accompanied with other symptoms resembling syphilis, the venereal character of the disease is to be suspected.

Treatment of Lippitudo.—The local treatment of this case in many respects does not materially vary from that recommended in common lippitudo. If the eye be much inflamed, leeches may be applied, or what is better, a branch of the temporal artery may be opened. If the inflammation of the conjunctival membrane be very considerable, it may be scarified, and a blister applied to the scalp. It will be necessary to wash away the matter with a warm decoction of poppies, injected under the eyelids. When the inflammation has in great measure subsided, the Ung. Hydrarg. Nitratis dilutum may be used, or a single drop of laudanum may be daily dropped between the eyelids. Lotions of the sulphate of zinc will be of great benefit. There is an objection to saturnine washes, from the lead being precipitated upon the conjunctiva, and occasioning great irritation. In obstinate cases one or two grains of the bi-chloride of mercury, dissolved in eight ounces of water, will be found a useful application, and along with the local treatment a mercurial course will be required.

(*To be continued.*)

CASE OF FISTULOUS COMMUNICATION BETWEEN THE RECTUM AND THE URETHRA.

By Frederick Francis Giraud, Esq., Surgeon, Faversham.

A man, aged 59, complained to me about two years ago, that he had difficulty in passing fæces, whenever there was the slightest tendency to costiveness, and that frequently he perceived wind to pass through his urethra. Upon an examination a stricture was found in the rectum, about three inches high, and it was ascertained that not only wind passed through the urethra, but sometimes fæculent matter also made its appearance at the orifice. It did not seem that urine found its way into the rectum, and therefore it was inferred that a fistulous communication existed between the urethra at its membranous portion, and the rectum. Sir Benjamin Brodie was consulted, who confirmed this view of the case, and advised that nothing more should be attempted than the daily passage of a rectum bougie, increasing gradually the size of the instrument.

An improvement slowly took place in the state of the rectum, and of late the calibre of the gut has become almost restored to its natural size. The fistulous communication between the rectum and the urethra remains the same, and a few weeks ago an unusual irritation was felt in the urethra, and very soon something alive made its appearance at the orifice; the patient removed it with his finger. On placing it in a wine glass half filled with warm water, the movements it exhibited shewed great activity, and by the alternate contraction and dilatation of its rings, and the protrusion of a vaginated proboscis, it soon arrived at the edge of the glass. The accompanying drawing of a magnified view shews its form, and it appears to be a species of Echinorhyncus.

Questions may arise, whether a similar creature to this might have occasioned the fistulous opening between the rectum and the urethra, and whether the stricture in the gut which is now nearly at an end, might not have originated from the local irritation?

CASE OF OBSTRUCTION OF THE BOWELS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

As the treatment of this case shews that the method used to preserve life may sometimes be the means of hastening death, and as it may offer a hint to your readers, I beg that it may find a place in your Journal, provided that you think it worthy of it.

Yours faithfully,
EDWARD WALLACE.

Carshalton, 24th Dec., 1847.

Mrs. P., a woman about 60 years of age, in the enjoyment of good health, and of active habits, was seized on the afternoon of the 30th of October last, with severe pain in the bowels, for which she took hot brandy-and-water; this her stomach rejected. She then had recourse to castor oil, which aggravated her pain; and as she returned this also, she took another dose, with the same result, after which, late in the evening, I was sent for, and found her under severe pain, with frequent

vomitings, but without other signs of constitutional disturbance. Under these symptoms I enquired if she had a rupture, to which she replied that she believed not, but on rubbing her bowels for relief she had then discovered a swelling in the groin. On examination, a tumour was discovered, of the size of a walnut, resting on Poupart's ligament, midway between the symphisis pubis, and the spinous process of the ilium. This, however, was an enlarged gland, and threw no light on the nature of her attack.

Calomel, and the common purging mixture, with opium combined, were ordered forthwith, and anodyne fomentations to be applied to the belly, and the same repeated early in the morning, if necessary.

31st. 10 a.m. My patient found some relief from the fomentations, but the medicines had aggravated the pain, and vomiting was more frequent, and attended with more pain. Finding therefore that anything of a drastric nature gave her this distress, I ordered her injections with castor oil, the saline aperient mixture, and pills with calomel and opium, to be given every two hours alternately.

5 p.m. No improvement whatever; and as the patient was much worn down by pain and continued retching, I thought it prudent to open a vein, in the hope that such an operation would render the aperients more efficacious. Fortunately, perhaps, for the patient, and owing to faintness, only three or four ounces were obtained. I then persevered in throwing up warm water, with a small quantity of castor oil, until at last two quarts were injected, and the fomentations were ordered to be continued.

November 1st, 9 a.m. I found the patient exceedingly weak, part of the fluid injected returned, and a large quantity of dark-coloured fluid thrown off the stomach. Since the injections of last night pain had ceased, her chief distress now being from frequent vomiting, and from restlessness, arising from weakness; her pulse fluttered; her sight was impaired; she could raise her eyelids with difficulty, and I apprehended that mortification had taken place. A pill, with two grains of calomel, and half a grain of opium, to be given every six hours; half a pint of thin gruel, with twenty minims of laudanum, to be injected every six hours; and a table-spoonful of beef-tea or melted jelly to be given frequently.

5 p.m. The patient remains the same, with the exception that retching is less frequent, and the quantity returned less also. The same means ordered to be continued.

2nd. 9 a.m. Has had some sleep; the pulse is more distinct; vomiting less frequent, though of the same quality. The same means to be continued.

5 p.m. Slight improvement in all respects except as to the torpor of the bowels; the stomach less irritable retching taking place only when its contents amounted to about half a pint.

3rd. 9 a.m. My patient had more sleep, and there was further amendment, with the exception of the absence of all evacuation from the bowels, when it was suggested by a friend of the family that air should be injected to an extent such as the patient could bear, and this was done accordingly.

5 p.m. No benefit was derived from the above-named operation, yet the patient had not lost ground since the morning.

4th. 9 a.m. The patient remained the same in all respects, except that the mouth became tender from the use of the mercury, and the fluid rejected by the stomach consisted of that which was taken, unchanged, but despondency had taken possession of the patient, who turned a deaf ear to all the encouragement offered to her. The plan of treatment to be persevered in, the calomel in the pills being reduced to one grain each.

5th. 9 a.m. No further improvement having taken place, it was agreed upon by the family and myself that I should go to London and have a consultation with Mr. Bacot, the result of which was, that a quarter of a drop of croton oil should be given every two hours until it provoked the bowels to act, which was not adopted, for at 5, p.m., I found since the morning, that my patient had gone through the day as usual, except that within the last hour she had passed a small motion with considerable flatus; this evacuation was in all respects of a healthy character. She was ordered to limit the use of the pill to night and morning, and to continue the injection of gruel and laudanum as heretofore.

6th. 9 a.m. Has had in the course of the night and morning two small motions of the same healthy character; has taken nourishment in a larger quantity; no retching, and has felt better in every respect.

5 p.m. All went on well. The pill was discontinued, and if twelve hours passed without an evacuation, the injection was ordered to be used.

7th, 8th and 9th. The patient improving daily. The stomach and bowels regained their healthy function, and by the latter end of the month she found herself able to attend to her domestic duties as before.

CASES FROM PRIVATE PRACTICE.*

By John Richard Wardell, M.D., Edin.;

Late President of the Royal Physical and Hunterian Medical Societies, Assistant Pathologist in the Royal Infirmary, Edinburgh, &c. &c.

Infanticide.

The condition of the lungs as discoverable on dissection has been long and deservedly considered one of the chief considerations in the medico-legal enquiries on infanticide. Harvey had certain notions concerning the conclusions to be arrived at from these organs, but afterwards Rayger and Schreyer confirmed the hydrostatic test, and to them is undoubtedly due the merit of its first establishment. In a court of justice the medical evidence would most assuredly be asked many questions relative to these organs, hence in the autopsies we can never be too precise and careful in our particulars.

On exposing the thoracic viscera, in both cases it is seen that the anterior margins of the lungs were found to overlap the pericardium almost to its

* Continued from page 67.

entire concealment, and in the female the diaphragm was less convex than it is when the lungs are in the fœtal state. When the child has been avowedly still-born, a very different state of things obtains; the thymus gland and pericardium are prominently in view; the lungs are quite back in the chest, almost at first giving the impression of their being absent; instead of being of a pinkish red, they are of a liver colour, feel dense to the touch, their edges sharp, and the sign termed crepitation is not present; the thorax is not so ample, and it gives the appearance of being sunken and contracted. "The chest of a full-grown child," says Dr. Traill, "which has not breathed, measures from two to three inches transversely, and from about two to two and a half inches from the sternum to the spine. When the same child has breathed, its chest will be from three to four and a half inches wide, and about three in depth."* In the first of the subjects calling forth these remarks, the colour was exactly similar to that noticed when respiration has been normally performed, except on the posterior inferior parts where there was distinct engorgement; the lungs filled the chest completely, nor was there any of that mottled appearance which is presented when the respiratory process has been but imperfectly carried on. On referring to Case No. VI., it is said "They were of a deep pink colour posteriorly, their anterior margins being of a much lighter hue." From these particulars above, it is extremely probable, if it be not affirmed indubitable, that in each natural breathing had been performed.

Dr. Traill gives the average weight of uninspired lungs at from 430 to 600 grains, and after breathing at 1000 grains; and touching the same question, Mr. Taylor thus states:—"The average weight of the lungs, *after respiration*, derived from three cases, was 927 grains, but in making an estimate of this kind much will depend upon the degree to which respiration has been carried." These remarks are very correct, because a child will maintain a kind of tardigrade existence, and thus live even days, when but a very small portion of the organs are distended, and if subjected to the hydrostatic test, they might in a great measure, and it has even been affirmed entirely, sink, where the child had lived. Mr. Taylor objects, and very reasonably, to the statistical tables of Lecieux, who, in his deductions has not made the requisite allowances for partial and imperfect respiration. It would have been decidedly more satisfactory if Lecieux had based his conclusions from the weights of children as much as possible the same, and where the lungs were in each thoroughly distended, but without these precautions his statistics are not nearly so valuable. The lungs of the female child weighed 813 grains, which is less than the averages of Traill and Taylor. Most of the authorities on the subject, it will be found on reference, weighed the bronchi and trachea as well, which was not done in this case, as I merely weighed the lungs themselves; nor was any ligature placed around the pulmonary vessels, some blood, therefore, would escape which ought to have been reckoned. Hence, if this escaped blood, the bronchi, and trachea, had also been added, certainly not less than other sixty grains would thus have been obtained, and the weight therefore might with confidence be stated at 873 grains. The weight of the lungs in the male was 812 grains, and thus remarkable to say, being but one grain difference in their weight. Surmising that the operator in this instance had weighed merely the lungs, as I had done myself, I wrote to Dr. Wright making the inquiry, and the following is a quotation from that gentleman's note:—"I have a distinct recollection," says he, "that the lungs were weighed with the bronchi, and the lower half of the trachea attached; and that a ligature was thrown around the root of each lung previously to its removal." The mean weight of these two cases is 842 grains. Taking the detailed circumstances into consideration, and recollecting that neither of the children were large infants, it must be inferred that this test was confirmative of the opinion of live birth.

The lungs may swim when respiration has never in the least degree been performed,—when putrefaction has taken place,—and when they have been artificially insufflated. In both these examples, the most cursory observation denoted that not the least decomposition had taken place, not only in the lungs, but in any part of the bodies; besides, it is well known to pathologists, that all the other viscera have a greater tendency to decompose than these organs. Within the last few weeks I was summoned by the coroner of the district to make an examination on a body then exhumed; and although some parts were passing speedily to decay, the lungs were as little altered in colour, consistence, and other characteristics, as I had ever known them where death had only preceded two or three days. If this had been the cause of their buoyancy, there would have been fœtor, discolouration, the absence of crepitation, and other manifest indications of the putrescent state, with unequivocal decay of the other viscera. When the lungs float from the gases generated in decomposition, they do not so lightly swim upon the surface, and the pleural covering is raised with blister-like elevations, which, on being punctured, readily collapse. Any one but little conversant with morbid appearances might at once, in each of these examples, have seen that no putrescency existed.

With regard to artificial inflation, it would be impossible, with any show of reason, to maintain even the probability of such having been had recourse to, in either Dr. Wright's case, or my own. When thus distended, the inflation is irregular, the air insinuates itself into the interlobular cellular tissue, and

* Outlines of Medical Jurisprudence, p. 71.

Dr. Hunter says that bullæ are produced, which run in lines. It would have been utterly impossible to inflate them, *in situ*, so thoroughly as they were distended in these instances, for even under the hands of an adroit operator, it is difficult to entirely fill them, and far more so by unskilful persons. The air will pass down into the stomach and bowels, and these organs are then found filled with air. It has been proved by experiment, that however perfectly the organs are artificially distended, such distention does not in any appreciable degree add to their weight; whilst on the other hand, the process of breathing makes them almost as heavy again. The forcing in of air rather tends to make their weight less, because it forces out some quantity of watery fluid. Another great test is, that the air thus transmitted can by pressure be perfectly expressed, and the lungs be deprived of their buoyancy; but when respiration has been performed, no degree of pressure, however powerful, can expel the air, and thus make them sink,—facts which have been particularly insisted upon by Beclard, and indeed by all recent writers upon the subject. In both these cases, as mentioned in the reports, even small sections of the pulmonary tissue, however powerfully compressed, could not be entirely deprived of air, and made to sink. The increased weight depends thus, from what has been said above, not merely upon distention; it is owing to the change in the circulation,—to the cessation of fœtal, and the institution of separate, life,—to the influx of blood, by which the vascular tissue proper to these organs, becomes normally distended with the vital fluid. When artificial insufflation has been attempted, the lungs are almost invariably but in part distended, the lower portions retain their fœtal characters, and when placed in water the inferior parts fall towards the bottom.

Some rare examples have been recorded where children have breathed before delivery, when the mouth of the child was at the os uteri, which is termed vagitus uterinus; and where inspiration has been performed while the head remained in the vagina; such has been called vagitus vaginalis. These cases, however, are mere possibilities, and when they have taken place it has been in exceedingly difficult, or, perhaps, it might be said, always instrumental labours. From the thorough manner in which the lungs were filled with air, there could be no plausibility of reason in the supposition that they were distended by the kind of breathing described, either in Dr. Wright's case, or my own.

There are cases recorded in which the fœtal lungs acquired a very considerable size from disease; but enlargement from such cause can be readily detected, for they are, when diseased, indurated, and present the characteristics known by the term hepatization; and if from emphysema, that state is also distinguishable. The mean weight of the heart in these two cases was 346 grs.

It has been maintained by some, especially by Brent, of Vienna, that immediately after the change in the circulating apparatus has ensued, the ductus arteriosus becomes manifestly altered; hence this has been called the Vienna test. The professor has with more confidence set forth this opinion than facts substantiate, because it does not invariably present the appearances which he has imagined never fail to follow the establishment of breathing. If this had been an infallible proof of inspiration, it must needs have been of paramount importance, and well-nigh rendered all other investigations supererogatory. In the first case the duct certainly was contracted in its central portion; in the second there was narrowing at the aortal end. In the female the ductus venosus was empty, but did not show other indications of change. Dr. Wright makes no mention of this vessel in his report, which is of little consequence where the child has existed but a short time, because the duct does not become very different for some days after birth. In both, the foramen ovale was carefully examined, but in neither was the orifice closed; indeed it is generally some days before it is filled up, and I have seen it patulous in *post-mortem* examinations of the adult, its value therefore, in a medico-legal point of view, becomes very questionable.

In conclusion to these imperfect remarks, a few points may be briefly reiterated. In these cases the length, weight, perfectly-formed nails, abundance of hair, together with other appearances, left not a shadow of a doubt that the children were born at or near maturity; whilst the perfectly expanded lungs, the colour of these organs, their consistency, buoyancy, general crepitation, weight, etc., the contraction of the aortic duct, together with other signs, gave indubitable evidence that the respiratory function had been for a shorter or longer time carried on,—or in other words, that they had supported an independent existence. The mark upon the neck of Case No. V.,—the excoriation, subcutaneous effusions of blood, frothy mucus in the bronchi, congestion of the lungs, bloody coagula discovered in the deep-seated parts of the neck, the considerable encephalic turgesence, and the effusion of dark fluid blood that escaped on removal of the calvarium, rendered it abundantly conclusive that the infant had been strangled; and if the suspicious circumstances under which the child was found, together with the appearance of the funis, be also taken into account, there could be no moral doubt remaining that the child had been feloniously destroyed. Such opinion being deposed, the jury after a deliberate review of the facts returned a verdict of "wilful murder against some person or persons unknown." With regard to Dr. Wright's case, there being no marks of violence, and the manner in which the funis had been divided, that is, its division taking place so near its umbilical insertion, rendered it *possible* that the

child might, according to the woman's statement, have been suffocated in the discharges, and as there was no further evidence of the graver accusation, she received the benefit of that possibility, and was therefore merely punished for concealment.

Through the kindness of my friend Dr. Browning Smith, of Kensington, who procured for me the body of a still-born child, is briefly presented to the reader the appearances where breathing *had not* been performed, and in these the apposite conditions will at once be manifest.

Post-mortem examination on the body of a still-born female infant, February 15th, 1848. Is a small child, but from the quantity of dark hair, the well-developed nails, on both fingers and toes, as well as from its general appearance, there is no doubt of its having been born at or very near the full period of gestation. The mother stated that it was within a few days of the natural time, and was a *primparous* birth; chest looks small and contracted; intercostal spaces, especially at the inferior anterior parts of the thorax, very distinctly depressed. On opening the chest, the heart and thymus gland are prominently presented to view; lungs occupy the posterior part of the chest, and when brought forward are condensed liver-like substances; upon being squeezed between the fingers there is not the least crepitation at any part of the organ, and on being thrown into water readily sink to the bottom. The lungs weigh together 365 [?] grains—right 203 grains, and left 183 grains, (without the bronchi or any of the trachea.) Heart rather small, and after it has been washed weighs 150 grains; ductus arteriosus and ductus venous flabby and uncontracted. On reflecting back the scalp some bloody jelly-like matter, in the sub-scapular cellular tissue, similar to what is generally observed consequent upon pressure during parturition; on exposing the external surface of the brain, the convolutions are seen normally developed, and upon making sections of the organ no præternatural vascularity is apparent. The other organs manifest their wonted characteristics.

If the reader compare the appearances discovered in this case with those above, the very diverse conditions of the chest, the lungs, and the ductus arteriosus, cannot but be at once apparent. In this there was no lapping over of the anterior margins of the lungs on the pericardium, but the heart and thymus gland, as mentioned, were prominently presented to the view. Again, the organs were of a dark liver-coloured red, not the bright pink as witnessed in instances where the function of respiration has been carried on; and instead of being buoyant, they quickly sunk to the bottom. In this example the pulmonary organs did not fill the chest, but occupied a very inconsiderable space, and on first opening the thorax it almost seemed as if they were really wanting, whilst the absence of crepitation, and their weight, exemplified the broad and wide difference between the examples contrasted. Regarding this illustration, then, as a negative proof of the conclusions arrived at above, it tends to confirm the opinion that Cases V. and VI. had respired, and consequently been self-existent beings; and so far as the first example is concerned, and of which I can more positively speak, there can be no sort of moral doubt at its being destroyed, and especially when the line on the neck, the great vascularity of the brain, together with other conditions, are also taken into account. There are some other considerations, perhaps, which might have been briefly mentioned in these imperfect remarks, that have not been adverted to, but as it is my intention to institute a series of enquiries touching certain points in the pathology of infanticide, I hope that in a future communication these will be fully embraced.

(To be continued.)

Hospital Reports.

CUMBERLAND INFIRMARY, CARLISLE.

SURGICAL CASES UNDER THE CARE OF W. B. PAGE, ESQ.,

(Reported by EVAN THOMAS, Esq., House-Surgeon to the Infirmary.)

CASE I.

DISLOCATION OF THE RIGHT HIP ON THE DORSUM ILII: REDUCTION AT THE END OF MORE THAN SIX WEEKS.

Robert H., a robust railway labourer, aged 22, was admitted from Crawford Mair, in Scotland, October 19th, under the care of Mr. Page.

He stated that while working on the Caledonian railway on the 4th of September, he was violently knocked down by a slip of earth falling upon him, he being at the time in a stooping posture, and when taken up he found that he was unable to move his right thigh. A surgeon who saw him immediately afterwards, detected the dislocation, and aided by fourteen men, made strenuous efforts to reduce it, but to no purpose, and since that time several "bone-setters" had made similar attempts, but with no beneficial result. Nothing had been done for three weeks prior to his admission, he having been persuaded that the limb only wanted exercising to become useful. He had struggled hard to crawl about with the aid of crutches, and was daily gaining more power on the limb. On admission the right leg was more than three inches shorter than its fellow, inverted, and the great toe resting on the left metatarsus. On examining the gluteal region, the nature of the injury was at once apparent, as the head of the femur could plainly be seen, and felt rotating, when the limb was moved, high up on the dorsum of the ilium.

After having been in a warm bath for an hour, in which he fainted, he was laid on a mattress on the floor lying on his back, his pelvis being kept steady by a jack towel placed around the perineum, and fixed to a hook in the floor. A bandage was applied above the knee, and gradual extension made with the pulleys in a direction across the opposite thigh, just above the knee. He was kept in a depressed state by the administration of repeated doses of tartar-emetic, and after nearly an hour was bled to about forty ounces. The limb was occasionally rotated during the period

occupied in the extension, and at the end of an hour and a quarter, just as the attempt was about to be abandoned, the head of the bone slipped into the acetabulum during a forcible rotation outwards of the limb. The thighs and legs were firmly bound together, and he was carefully laid in bed, but passed a very restless night and made several attempts to rise in bed, which from the confinement of his legs was a work of some difficulty.

On the following day the leg was again found to be shorter than the other, to the extent of more than an inch, with all the symptoms of the previous day, but in a lesser degree, and on examination the head of the bone could be plainly felt resting on the ilium, close to the margin of the sciatic notch. The limb was again subjected to extension, he being now laid on the sound side, the right limb being drawn in a direction across the middle of its fellow, and a towel was placed round the upper part of the thigh and the neck of an assistant, with a view to raise the head of the bone over the margin of the acetabulum. At the end of half an hour the reduction was accomplished. A broad belt was placed around the pelvis, the knees and ankles were firmly bound together, and he was kept lying on a mattress for five weeks. At the end of six weeks he was allowed to get up, both limbs were found to be of equal length, and almost of equal strength.

December 4th. Can walk nearly as well as ever; scarcely a halt perceptible; every motion of the limb is perfect and free from pain.

9th. Discharged to go into Staffordshire; limped but very little, and this he says he has always done, owing to some injury to the ankle received many years since.

Case II.

DISLOCATION OF THE HUMERUS INTO THE AXILLA: READY REDUCTION AT THE END OF ELEVEN DAYS UNDER THE INFLUENCE OF CHLOROFORM.

James M——, an athletic railway labourer, 30 years of age, was admitted from the summit cutting on the Caledonian railway, January 8th, under the care of Mr. Page.

Eleven days before as he was walking upon a scaffold, carrying on his shoulder a load of bricks, his foot slipped, and he fell from a considerable height head foremost to the ground. His left shoulder was the part chiefly injured, but the surgeon to whom he applied believed it to be only severely contused. When he appeared at this hospital the special characteristics of dislocation into the axilla were sufficiently evident, and in addition, there was paralysis of the motor and sensitive nerves of the limb, from the long-continued pressure of the head of the humerus in the axilla.

An attempt was at once made at reduction by means of the heel in the axilla, but without any sensible effect being produced. Two hours after he was seen by Mr. Page, who directed that the same means should be again employed, the patient being placed under the influence of chloroform; accordingly, the man being placed on a couch, about a drachm sprinkled on a handkerchief was held before his face, which speedily induced a state of perfect unconsciousness. The heel was placed in the axilla, and extension made from the hand, the operator receiving no additional aid from pulleys, or any other person, and in two minutes the head of the bone resumed its lost seat on the glenoid cavity of the scapula. After the first few inhalations there was a great tendency to violence, which continued for some seconds, and during the whole time that extension was continued he talked incessantly, and most vociferously. He soon recovered his sensibility, and said that he had dreamt he was falling down a precipice, but had felt no pain.

This man complained of great pain in the head, and a sense of confusion, for two days after the inhalation, and altogether appeared to suffer more inconvenience from it afterwards, than any other of the large number of persons who have been subjected to its influence in this hospital, possibly from the circumstance of the chloroform having been administered while he was in a recumbent position, his head at the time not being at all raised.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, FEBRUARY 23, 1848.

We beg to direct the attention of our readers to the following important resolutions which Lord Ashley has announced his intention of shortly bringing before the House of Commons. They are founded on the evidence given before the select Committee on Poor-Law Medical Relief, in the year 1844, and seem well calculated to obviate several of the very serious evils by which the system now in operation is beset:—

"1. That it is the opinion of this House, that the Poor-Law Commissioners should cause a list to be made out, by the proper officer in each parish of a Union, of the poor who may be entitled to attendance from the medical officer of the Union; and that all such persons shall be at liberty to ask the assistance, without previously obtaining an order to that effect from the relieving officer, overseer, or other person, when so seriously ill as to be unable to leave their homes. That the poor thus applying shall not be entitled to such medical attendance beyond twenty-four hours, unless they obtain the signature of the relieving officer to the printed order usually issued by him to the surgeon; but which printed order shall in such case be given by the surgeon to the poor man in the first instance, to be carried by him or his friends to the relieving officer for his information and counter-signature, as an acknowledgment of the fact of such medical relief having been asked for and obtained.

"2. That all casual poor requiring medical attendance be treated in a similar manner, the surgeon being at liberty to refuse further attendance, if the counter-signature of the relieving officer be not obtained.

"3. Every woman claiming medical assistance from the parish in consequence of being pregnant, shall be entitled, in all cases, to the aid of the medical officer

with her first child, and also with the second or others which may follow, provided she present a certificate from the medical officer who attended in her previous confinement, stating that circumstances had occurred in it out of the ordinary and natural course of events, which render it desirable that she should have medical attendance on the next occasion of delivery.

"4. That, in the event of its being necessary to destroy the child in order to save the life of the mother, the Union surgeon shall be at liberty to seek the assistance of another competent practitioner, if he see fit, before the necessary operations are performed, and who shall be paid for the assistance rendered, on producing to the Union or proper officer the joint certificate of the Union surgeon and himself that such consultation and aid were essential, previously to the expected, legal, and necessary deprivation of life.

"5. That no medical person be appointed surgeon or medical officer to a Union unless he possesses a diploma in surgery, and a degree, diploma, or licence in physic, from one or other of the Universities or Colleges of Physicians or Surgeons, or Societies of Apothecaries of the United Empire, legally entitled to grant respectively such licences, diplomas, or degrees; and that if, under any circumstances, it should be found necessary to employ unqualified persons, such unqualified persons must have a special permission granted by the Poor-law Commissioners, under their handwriting, with the reasons for such permission annexed; all such permissions to be annually laid before Parliament at the commencement of the session.

"6. That from and after the month of March next, the appointment of medical officers of Unions shall be permanent during good behaviour, they being removable only by the Poor-law Commissioners, whose decisions shall be final.

"7. That it is expedient that medical inspectors be appointed by the Poor-law Commissioners, or by the Secretary of State, or with his sanction; one to each district to which an Assistant Poor-law Commissioner or Inspector is attached, at a salary not exceeding four hundred pounds a year, exclusive of travelling expenses, and exclusive of an allowance of a clerk, if the duties should require one.

"8. That the duty of the medical inspectors should be to inspect and report on the medical treatment of the poor of the different Unions, and on the fitness of the medical men appointed by the Unions; to inquire particularly into the treatment of the sick poor in the Union houses, and to regulate such treatment; to inquire into and report on the diets and healthful condition of the poor within them generally, together with such other sanitary duties of every kind as may be required of them by the Secretary of State, or by the Poor-law Commissioners; and particularly with respect to the number of medical officers who ought to be employed in each Union, and the salaries which ought to be awarded to them for their services in each particular Union, or part of a Union, in the district."

The first four of these resolutions are manifestly intended to mark out the objects for the receipt of medical assistance, and at the same time to place the initiatory step in the granting of this assistance in the hands of the proper officer,—the District Surgeon. Much valuable time will thus be saved, especially in cases of urgency; the medical officer will be spared the alternative of either refusing immediate assistance when such is required, or supplying it at his own proper cost, while the relieving officer will be accountable, as he ought to be, for the withdrawal of that assistance in all cases in which he may refuse to authorize its continuance.

The sixth resolution is absolutely necessary to place the medical officers in a position of independence, and to enable them to do their duty by the objects of their charge without fear or risk of ulterior consequences to themselves.

The seventh and eight resolutions provide at last a competent authority for the due regulation and efficient superintendence of all that belongs to this department.

These resolutions, if sanctioned by the legislature and duly carried out, cannot fail to place the entire system of medical relief to the sick poor on a greatly-improved footing. They appear sufficiently definite to meet the purposes required, and involve no complex machinery to impede the working of them. There is, however, an objection to the fifth resolution, to which we have not alluded, and which we shall be glad to see removed. This resolution is declaratory of the qualification of the medical officers, and very properly provides in the first instance, that such officers shall be duly qualified both in physic and surgery. There is, however, an exceptional provision introduced, of which we can neither see the necessity nor admit the propriety. We cannot conceive any circumstance, where, in this country at least, it would become necessary to employ unqualified persons, and still less in which it would be either expedient or consistent with the justice due to the public to in any way authorize or countenance the employment of such persons in the discharge of a public trust. We hope that the esteemed nobleman who proposes to introduce these resolutions into the House of Commons, will see fit to strike out the latter part of the fifth resolution before bringing them forward in the House, so that his measure, which will so justly entitle him to the gratitude of the poor, and the thanks of the medical profession, may be in all respects unexceptionable.

Review.

Du Muscle Rotateur Externe de la Jambe, et de la Luxation consecutive du Genou en dehors et en arrière. Nouvelle Methode de Traitement des Ankyloses Angulaires du Genou. Par le Docteur F. PALASCIANO, &c. &c. Lyon. 1847. pp 63.

On the External Rotator Muscle of the Leg, and on Consecutive Luxation of the Knee outwards and backwards, with a New Method of treating Angular Ankylosis of the Knee-joint. By Dr. F. PALASCIANO.

The memoir which has been recently presented to the Academy of Lyons under the above title, has for its object to point out an action of the tensor vaginæ femoris muscle, supposed by the author to have been hitherto overlooked, and to display its influence in the production of the consecutive dislocations of the knee-joint. It has also the further object of illustrating the success of a line of treatment based upon the physiological conditions of the above muscle.

It has generally been thought that the actions of the knee-joint are limited to those of simple flexion and extension, and that the leg is not endowed with the faculties of pronation and supination possessed by the forearm. This opinion, which has originated from observing the rotations of the leg when extended, is shewn by the author to be erroneous, and he determines, as any one may convince himself in his own person, that if the leg be flexed upon the thigh, rotation of the limb may be effected to a very considerable extent indeed.

The above power of rotation was, however, not unknown to the Webers, though they attributed it to the biceps femoris and popliteal muscles. The originality of M. Palasciano consists in his believing that the rotation outward is produced by the action of the muscle known to English anatomists as the *tensor vaginæ femoris*, but which he calls the "external rotator" of the leg.

The author's application of these anatomical views to the therapeutics of consecutive dislocation of the knee-joint, is both ingenious and important.

Although dislocation of the knee, as a sequence of scrofulous or other disease, may occur in various directions, it is well known that the most frequent form is that in which the head of the tibia is carried behind, and external to the condyles of the femur. In this apparently simple disposition of the parts, however, several adjuncts are to be observed. 1. The leg is more or less flexed upon the thigh. 2. It is abducted. 3. It is rotated outwards. 4. The patella is also dislocated outwards. The deformity therefore, in fact, consits of five parts, three of which,—namely, the flexion, rotation, and abduction, may be simulated in the healthy joint; the two others, the displacement of the tibia and patella, are necessarily morbid.

The great merit of Mr. Palasciano's memoir is the manner in which he makes his antomical knowledge subservient to the removal of these lesions. If we bear in mind the different elements of which the deformity in question is composed, it must appear plain, that to remedy this deformity effectually, two things must be accomplished; first we must remove the abnormal positions of the limb,—the flexion, the supination, and the abduction; and secondly, we must reduce the dislocation of the head of the tibia, and of the patella. On these points we give the remarks of M. Palasciano:—

1. To replace the morbid flexion of the limb by extension, we may have recourse to a simple manipulation, the use of apparatus, and if these fail, to section of the tendons of the ham.

2. To remedy the supination of the limb, it becomes necessary in most cases to divide the tendon of the "external rotator muscle." This operation is performed by the subcutaneous section, taking care at the same time to divide the tendon of the biceps.

3. Having thus proposed the remedy calculated to fulfil the two first indications, we have now to examine the questions relative to the third.

When the tibia is extended upon the thigh, it cannot be inclined to the right or left, but if it be flexed upon the femur, these lateral movements are made with facility. The movement, which is that of abduction, is encouraged by the state of supination, and acquires its greatest degree when the leg is at the same time flexed and turned outwards. This state cannot be remedied, unless the supination and flexion be previously rectified; pressure will then be effectual.

4. We come now to the most difficult part of the problem, the reduction of the displaced tibia and patella. The patella, when dislocated, is found in front of the outer condyle, to which it eventually becomes anchylosed, and some time before the same union takes place between the femur and tibia. The first thing, therefore, to be accomplished, is the disruption of this union. Until lately this would have appeared an impossibility, but M. Dieffenbach and our author have proved that it can be done with effect and safety.

Dieffenbach was in the habit of causing the rupture of the bony union by forcibly flexing the leg, and thus causing the ligamentum patellæ to act forcibly upon the bone. M. Palasciano modifies the operation by previously dividing the tendon of the rectus femoris. This is, doubtless, at first sight, a bold proceeding, but considering the circumstances attendant upon the deformity it is intended to remedy, is we conceive worthy of trial. It is to be remembered, however, that this section is not sufficient in itself, but must be associated with division of the biceps and external rotator muscles, as before mentioned. In this manner M. Bouchacourt has recently relieved a case of this spontaneous dislocation, the woman being previously rendered insensible by æther.

5. When the bony anchylosis has been disunited, the limb is to be maintained in a suitable position by mechanical contrivances.

So much for the ingenious operation devised by M. Palasciano. It remains to be enquired how far the patient is benefitted as regards locomotion; what are the accidents which such apparently rough treatment

may induce; and what are the contra-indications? Our space, however, will not allow of a very minute discussion of these questions, but if we are to believe the author, the inflammatory symptoms are slight, and the patient gains a very useful limb in favourable cases. Certain it is that the genius of Dieffenbach has caused us to look with complacency upon operations from which we should formerly have recoiled; and the advantages afforded by æther and chloroform, by enabling us to put physical pain,—the great contra-indication to so many operations,—entirely out of the question, bring within the domain of surgical interference numerous ailments, which, but for that invaluable discovery, must for ever have been considered unapproachable.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

COMMUNICATIONS.

[The following communications have been forwarded by Mr. Crompton.]

By A. Wood, Esq., F.R.C.S., Rochdale.

An experience of some thirty years, derived from a reasonably extensive practice, has convinced me that every case of burn, to be treated successfully, must be dealt with on its own merits, as regards *extent* and *degree*, not forgetting the age, habits, and constitution, of the patient.

I can explain my meaning better by supposing a few cases of different degrees of severity, than by answering your queries *seriatim*, and with your permission I will do so. To begin with the mildest case. A lady, sealing a *billet-doux*, scorches her finger with the taper; acting, as most ladies do, from impulse, she instantly plunges it into cold water, and in so doing I maintain that she does the very best thing possible. By alternately plunging it into cold water, and blowing upon it,—by applying cold, in short,—she puts a stop to the increased action of the vessels of the part, and consequently to the heat and pain. A surgeon does precisely the same thing by irrigating it with spirit-wash, by means of a little lint wrapped round the finger. In half an hour the case is cured. The cuticle may peel off in a day or two, but the patient suffers no further inconvenience.

My next case shall be one where a maid servant unwittingly plunges her hand and arm into a pail of boiling water, or a pan of boiling liquid falls off the fire upon a child on the hearth. Here is a very different case to the former one, and requiring very different treatment. In the child's case especially, the extent of injured surface renders the cold water both locally and constitutionally inadmissible. The patient is already in a state of rigor, and any extensive use of cold water would, in all probability, so depress the powers of life, as to risk the production of sloughing, where otherwise the result would have been merely destruction of the cuticle with inflammation, and possibly slight ulceration, of the cutis and cellular tissue. Many years ago, when flour and cotton first came into vogue, the following case occurred to me, and since then I have treated all similar cases in the same manner, and, making allowance for circumstances, with the same result. A maid servant, tired with her work, lay down on the hearth late at night, and a pan, containing about three gallons of boiling water, fell off the fire, covering her neck, bust, and arms. I saw her immediately; she was in extreme agony, and extensive patches of vesication had already formed. She was immediately dredged with flour, and folded up in *finely carded* cotton wool. She took two doses of calomel and opium, and as she was of a very inflammatory habit, sulphate of magnesia was given freely for two or three days. She suffered no pain after the night of the accident; there was considerable exudation from under the edges of the dressing, which was not removed for eight days, when it was carefully detached, having formed a complete mask. It brought with it the whole of the cuticle, but there was not the slightest abrasion or ulceration of the cutis. At my request she wore a white muslin neckerchief, but at the end of a week it had not a mark or stain from discharge upon it. She was in fact well, if we except a somewhat deep efflorescence co-extensive with the injury.

My third class of cases is, alas! too often illustrated by children's clothes taking fire. Here we have both deep and extensive destruction of the life of the injured parts, the dusky yellow colour and total insensibility of the skin shewing too plainly that sloughing is inevitable. Surely no one who reflects on the requirements of such a case would apply flour and cotton here, much less cold water. The patient is in a state of perfect collapse, and laudanum, ammonia, and brandy, will be imperatively demanded internally, while hot spirits of turpentine on flannel bandages, or poultices of spirits of turpentine and oatmeal, will form the best external application, removing the bandages as seldom as possible.* I have little faith, however, in particular external remedies in these extreme cases. The treatment must be constitutional, and directed entirely to the alleviation of pain and support of the patient's strength. It has often occurred to me in cases of this sort, at the end of five or six weeks, when the sloughing is over, the granulations healthy and abundant, cicatrization going on rapidly, and the patient's strength improving daily, to witness a sudden diarrhœa come on, which has destroyed the patient in a few hours. How this is to be explained except on the ancient doctrine of revulsion, I do not know. I think I have observed it most frequently when the abdomen has been the seat of the injury. Another circumstance has often struck me in these miserable cases. A child among the poorer classes, eight or ten years of age, has, up to the time of the accident, been heavy, dull, and stupid in character, to a degree almost denoting the absence of the intellectual faculties. Its countenance

* In a few days these may be changed for a mixture of equal parts of linseed oil, lime water, and spirits of turpentine, the quantity of the latter gradually decreasing; and at length ceratum resinæ, or calaminæ, and when practicable, bandaging.

has been a true index to the mind from its entire want of expression. In one month it is quite an altered being. The features become unnaturally old and sharp looking, while its perceptions and intelligence are quickened and developed in a remarkable degree. Probably the same amount of suffering from any other cause might have the same result, but it has not fallen to my lot to witness it.

I have seen many cases of burns from coal-pit explosions, but I do not know that they call for particular remark; they are generally very extensive but not deep. The constitutional symptoms are always severe, and in many instances the patients die comatose about the third day. Whether the *extent* of the injury,—often occupying the whole body,—by the shock it gives to the constitution, has any share in the fatal result, I will not say, but it seems probable. There is often also a great deal of bruising caused by the sudden expansion of the air driving the body of the sufferer against the roof and floor of the mine, and this may add to the danger. Generally speaking, they will fall into my third class of cases, and will require stimulants both externally and internally.

By T. M. GREENHOW, Esq., F.R.C.S., Senior Surgeon to the Newcastle Infirmary.

It is a somewhat extraordinary truth that, though no class of accidents is more frequent than burns and scalds, the principles on which their treatment ought to be conducted is still so unsettled, and that your inquiries amongst the members of the profession have already brought out the advocacy of the most opposite plans. Without believing that I can add much to the settlement of such discrepant opinions, I cannot help offering you a remark or two on the results of my experience in such accidents, of which, I regret to say, it has been my fortune to see many severe and fatal cases; and, as I have either myself tried or witnessed the effects under the management of other surgeons, of every plan of treatment hitherto proposed, you will perhaps think my experience and observations on this important and interesting subject not improperly brought before your notice.

I may premise a word or two on the necessity of distinguishing, with some degree of accuracy, in entertaining the value of any plan of treatment, the extent and intensity of the injury sustained. When slight and superficial, any plan will prove successful. When very extensive and deep, none will succeed in saving life, though suffering may be alleviated; and it is in intermediate cases chiefly that discrimination is required in the choice of remedies.

1. The application of oil of turpentine has, according to my experience and observation, afforded the greatest relief from suffering, and been most successful in establishing a new and healthy action in parts extensively and deeply injured, by the application of excessive heat. The best form of application is [turpentine] thickened with Ung. Resinæ; and I have found in extensive burns, that lawn or silver paper, dipped in this when warm, has been a very convenient and successful preparation method of employing it. The paper adapts itself well to the injured parts, and may be replaced, or deficiencies repaired, as often as may be required. When suppuration has been established, an ointment with Creta has been found by myself the most soothing and successful successor to the turpentine dressing; and, at a more advanced stage, when the healing process is apt to become nearly stationary, it often receives a useful stimulus from a lotion of camphor mixture, one pound, tincture of opium and solution of lead, each, one drachm. The part must be covered with lint dipped in the lotion, and protected with oil silk and a bandage.

2. Cold applications do well in slight burns, and I have found them especially useful in burns of the face, accompanied with extensive injuries of other parts. In some cases of this sort from the explosion of gunpowder, I have employed lint dipped in cold water successfully, the other injured parts being dressed with turpentine, as before described. A severe example of this kind is at present convalescent in the infirmary of this place. The nature of the part, and necessarily exposed condition of the face, render the cold water dressing extremely convenient, and of easy application.

3. In slight burns without vesication, cotton or flour answers well. I may add that, when the injury is so general and severe as to forbid all hope of recovery, to envelope the entire person in cotton is perhaps the most comfortable plan that can be pursued.

4. When the nervous system has received a great shock, internal stimulants are necessary, and opiates are often of great service. Subsequently the diet ought to be liberal, and quinine is useful as a tonic.

5. On the chest and abdomen burns of equal extent are attended with more hazard than on the extremities.

6. Contracted cicatrices are best prevented by the *non-application* of escharotics. The exuberant granulations attendant on burns are the process employed by nature to ensure an adequate extension of new skin. If this process is uninterrupted, the cicatrix becomes smooth and even, and the subsequent contraction is always increased in proportion to the destruction by caustics, of the healthy, though at first sight, perhaps, apparently too bountiful, granulations.

7. Of *post-mortem* appearances in cases of burns I have no adequate experience.

8. When the injury is extensive and deep, especially when occupying a large portion of the trunk, and in very young subjects, the prognosis is always unfavourable, though the issue is not necessarily fatal. Extensive burns of this description are not unfrequently succeeded by phthisis, even when the patient appears convalescent, as regards the immediate effects of the injury.

9. Cicatrices are best treated by separation from the subjacent textures by a broad incision and subsequent careful dressing, with the use of mechanical means for preserving or restoring the natural relation of parts which have been præternaturally approximated.

10. The best preliminary treatment of burns is to bathe assiduously the injured parts with oil of turpentine.

By Daniel Dorning, Esq., Surgeon, Swinton.

In advocating the use of flour in burns, my testimony will not be duly estimated, except I state that before I entered upon practice on my own account, I had been accustomed to see burns and scalds treated by another method. I was an apprentice to Mr. Robert Thorpe, one of the surgeons of the Manchester Royal Infirmary, in which institution burns were formerly treated as follows:—The Linimentum Terebinthinæ of the London Pharmacopœia, was kept in readiness spread upon tow, and when a burn was admitted, the tow (thus armed) was applied, and the dressing repeated daily until a cure was effected, or as was frequently the case, death terminated the patient's sufferings.* Just before settling at Swinton, I had read a pamphlet on the efficacy of flour in burns and scalds, and was very much struck with the facts contained in it, and shortly afterwards having been called to some colliers who were severely burnt by an explosion in a mine, I determined at once to make a trial of it. Accordingly, I applied it to the patients very freely, and was so much surprised at and so well satisfied with its effects, that I have continued to use it ever since. It is now upwards of twelve years since I commenced practice, and during that period I have again and again been called upon to attend colliers burnt by explosions in the coal mines, which in this neighbourhood are of very frequent occurrence, and during the whole of this time I have employed flour as a dressing, except in one case, when it occurred to me that I would apply flour to one arm, and cotton to the other, (both equally severely burnt,) in order that I might judge which was the best. The arm to which the flour was applied healed somewhat more rapidly than the other, and with less pain to the patient, thus confirming my impression of the great value of flour as a dressing in burns. I now use it in *all* cases be they extensive or the contrary. In the slighter cases, I think its effects are more satisfactory even than in the severe. When the burn is upon the back I keep the flour in apposition by means of cotton, which I procure in long flakes, "carded," and apply from the shoulders to the waist, and then crossways round the waist, so as to effectually retain the flour upon the burnt surface. The flour must be of the *best quality* and applied freely. In December, 1843, I attended two of the Earl of Ellesmere's colliers, at Worsley, which were dressed with an inferior kind of flour furnished by the patients; they were proceeding less satisfactorily than I could have wished, I therefore procured some *fine flour* in my own neighbourhood, and was surprised at the improvement the change had effected in a few days. I apply the flour with a "dredger," and allow it to "cake," simply directing the attendant to remove any discharge with a piece of soft old linen, or cotton wool, and not to disturb the "cake," but allow it to become detached of itself, when it must be removed, and the raw surface again covered with flour; and this process must be repeated until the "cake," on detachment, leaves a healthy surface, which it generally effects in fourteen or sixteen days. The pain produced by flour is, in my opinion, considerably less than is produced by any other mode of dressing, and most certainly not a *tenth* part so severe as the dressing with Linimentum Terebinthinæ, above alluded to, occasions. There is also considerably less risk of contractions following the cicatrization of burns cured by flour, than those cured by other means. I may state that next to flour, I consider cottou the best application in burns.

The ulceration remaining after severe burns I heal with Ceratum Calaminæ, unless it is in the vicinity of the hands or face, when I continue the use of flour; and in a case, (Samuel Harmer, of Pendlebury,) which fell under my care in March, 1844, in which the backs of both hands were ulcerated, I am convinced that subsequent contraction was prevented by steadily persevering in its use for nine weeks. In this case I was induced to persevere in the use of flour, from its similarity to one I had been called upon to attend in August, 1840, (that of Margaret Lloyd, of Pendlebury,) which had been six weeks under the care of another medical gentleman, and during that time dressed with Ceratum Calaminæ. I continued the same treatment until an attack of illness, which confined me to the house five or six days, occasioned her removal to the Manchester Royal Infirmary, where the cure was completed; but subsequent irremediable contraction of the fingers took place, and I have little hesitation in recording my opinion, that the result would have been the same in Harmer's case, if I had pursued a similar plan of treatment.

In the internal treatment of burns, I administer opium freely;—to an adult, three grains, as soon as called in, and repeat it in one grain doses, night and morning, and more frequently in very severe cases, at the same time exhibiting the Liq. Ammon. Acet., with Spt. Æth. Nitr., and sulphate of magnesia, every four hours, until the bowels are acted upon, after which I continue the mixture, without the salt. Opium I find necessary through the whole of the treatment, and when the fever has subsided, I prescribe it in combination with tonics.

By John Higginbottom, Esq., Surgeon, Nottingham.

In conjunction with my professional brethren I send you the result of my practice in burns and scalds.

1. In the early part of my practice I used Kentish's plan for burns and scalds, considering it at that time the best method of treatment. For the last twenty years I have preferred the application of the nitrate of silver, particularly in the first and second class of burns and scalds, for the following reasons:—

1st. The nitrate of silver in its application does not appear to increase the pain of *recent* burns or scalds, but soon after the suffering is much diminished by its subduing the heat and burning pain.

"Fire cools fire, in the scorched veins of one new burnt."

2nd. It most effectually excludes the air from the injured parts, and there is at once a covering superior to any other, formed and composed partly of the very surface itself.

* This was not Dr. Kentish's method of treatment.—S. C.

3rd. The nitrate of silver has the peculiar property of preventing subsequent inflammation, vesication, ulceration, and sloughing, therefore the burn or scald is limited in its extent, diminished in severity, and consequently less dangerous, for the danger is generally in proportion to the extent of surface destroyed.

4th. After the application of the nitrate of silver, the parts should be exposed to the air if practicable, to form an adherent eschar; this will be found invaluable in burns and scalds of the face, neck, breast, and abdomen, the latter being protected by a fracture-cradle when in bed, which will defend the parts and facilitate the formation of an adherent eschar. If, from accident or any other cause, the eschar should be removed, a repeated application of the nitrate of silver will be necessary.

5th. Where the parts cannot be exposed to the air to form an adherent eschar, as on the back, &c., the nitrate of silver must be applied, and afterwards covered with plasters of the neutral ointment,—the Unguentum Plumbi Compositum, (London Pharmacopœia,) spread on linen, and then secured tightly by a linen bandage. The dressing must not be removed before the fourth day, at the same time allowing any adherent dressing or eschars to remain until they separate; after the separation, should there be any sore or inflammation, a slight application of the nitrate of silver, or black lint,* may be applied, with or without the neutral ointment. The dressing may be repeated every third or fourth day, as required.

6th. I prefer the application of the *concentrated* solution of the nitrate of silver in burns and scalds, applied in the same way as I have recommended in the cure of erysipelas. [See *Provincial Journal*, 1847, pp. 458, 532.] The surface should be made as clean and as *dry* as possible; any vesications or loose cuticle must be removed. A convenient instrument for the application of the solution is a small piece of sponge, secured on the eye of a common silver probe.

2. ———

3. ———

4. Opiates. Would not the inhalation of chloroform be worthy of trial, particularly during the first dressing of the patient?

5. Burns on the chest and abdomen in children. I have seen a small burn on the scrobiculus cordis of several days' standing, occasion convulsions and death, which I think would have been prevented by an eschar being formed upon the part to defend the nervous papillæ.

6. Cicatrices are always prevented when an adherent eschar can be formed with the nitrate of silver on the scalded or burnt surfaces from the commencement.

7. ———

8. Favourable or unfavourable generally according to the greater or less extent of the skin destroyed. Unfavourable in children when the chest or abdomen is scalded or burnt.

9. I have had no cicatrices of consequence, since I adopted the treatment in the first question.

10. To clothe with woollen garments;—even aprons and pinafores for children of the same material. To envelope the patient in a soft linen sheet, to defend the body from the air, and if cold to cover over with a blanket; this will allow the surgeon to have a clear surface, that he may use his own method of treatment.

11. In the third class of burns I use the sulphate of copper for the suppression of granulations, but I have had less occasion for after-management since the use of the nitrate of silver. If debility,—particular attention to the digestive organs, change of air, nutritious food, quinine, compound infusion of orange peel, &c.

12. ———

By Samuel G. Sloman, Esq., Surgeon, Farnham.

In all cases of burns or scalds, I consider the most important point is to protect them from the influence of the external air. In slight cases I generally use the liniment—Oleum Lini cum Liquore Calcis, particularly when there is any inflammatory action, which it has always appeared to me to relieve. In more severe cases, when the destruction of the tissues is greater, I use the Unguentum Zinci or Resinæ: the former I have found very useful. When there is sloughing or gangrene I use a dressing containing turpentine. I always vary the treatment according to the extent and situation of the injury, and the constitution of the patient. In young and healthy subjects I have always found simple dressings answer best. In old subjects of feeble habits, I prefer a more stimulating plan. I have always considered the *internal* treatment the most important part. In all the fatal cases of burns that I recollect having seen, the patients have died very soon after the accident, and evidently from the effect produced upon the nervous system, and not from the exhaustion produced by the excessive discharge after suppuration has commenced. I prefer extract of henbane in a full dose, with camphor, in ordinary cases, which appears to allay the irritability of the nervous system without deranging the secretions; in more severe cases I give Dover's powder, or morphia, with ammonia, and where the destruction of parts is extensive, I always support the system well with beef tea, &c. I have found bandaging accelerate the healing process very much, and at the same time keep down the granulations, it being only necessary to use escharotics for the edges of the wound. I always use the Cupri Sulphas. I do not like the use of cotton, and have seen much mischief arise from it, and much unnecessary pain caused by it; neither do I like flour, as it is so apt to cake, and thus cause heat and irritation to the part. Inasmuch as it is very important to preserve the cuticle as far as possible, I think some liquid application is the best. When there is any probability of contraction taking place from cicatrization, I apply splints, or such other apparatus as may be suitable, to the part affected, as soon as the healing process commences. I should think the best application to recommend to the public for immediate use in all cases of burns and scalds would be oil, linseed oil if possible.

---

* *Linteum Nigrum.*—R. Argenti Nitratis, dr. ij.; Aquæ Destillatæ, oz. iv. Misce. Fiat Solutio. Saturate an ounce of fine lint in the above solution; then let the lint be exposed in an open shallow vessel, to allow it to dry by evaporation.

By G. F. Wills, Esq., Surgeon, Crewkerne, Somersetshire.

Mr. Wills states that "in the few cases where he has seen stimulants used he has not approved of them, except in deep burns, and there they were not very efficacious." He considers cotton wool an excellent application, the chief objection being the feeling of drynesss which the patient complains of in the parts to which it is applied.

"The most pleasant application to the patient is," he observes, "in my opinion, warm water dressing and oiled silk. It is easily changed, is not heavy, keeps the parts moist, encourages *even* and *level* granulations, and the formation of cuticle. Poultices are too weighty, and very troublesome to be removed; barm or beer-ground poultices are beneficial in deep burns, but either may be applied, on rags, and covered with oiled silk. Flour is a good remedy, but as is also the case with wool, it sticks to the sore, and causes a very unpleasant, and often a very painful, sensation of dryness and roughness, and I have been obliged to remove the flour, and apply the warm water and oiled silk. Oil is very inferior to flour or wool. When the granulations are too exuberant, a lotion of nitrate of silver, or sulphate of copper, (*one grain* to *one ounce* of rose-water,) may be applied with a brush once a day, or the lint may be dipped in it instead of warm water, and applied under the oiled silk. When burns occur in the inguinal or femoral region, care must be taken lest the scrotum become united to the part.

"I should be glad to have your opinion, or that of any member, on the following case:—

"About five years ago, a child, (female,) aged nine years, had a severe burn of the right thigh. It healed very well for some time, but when there was a sore left, about four inches broad, and six long, it became stationary, and has remained so more or less ever since, notwithstanding all the many applications which have been made. Sometimes it is rather larger, sometimes less. It always looks well, and if a stranger saw it he would say it was healing very well. Sometimes it bleeds, but the granulations always seem perfectly healthy. The girl is in good health, and stout, but latterly there has been something approaching vicarious menstruation, (the catamenia never having appeared,) for about every month there is rather an increase in the size of the sore, and bleeding occurs.

"What can I do to cure this patient?"

[Further communications can be forwarded to Mr. Crompton, Surgeon, Manchester, or to the Editor of the *Provincial Journal*.]

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY,

Januuary 6th, 1843,

James Russell, Esq., in the Chair.

Mr. Russell presented two cases of perforation of the stomach, in women; and a case of rupture of the left Fallopian tube, during the passage of an ovum, which occurred in a young newly-married woman, who died after a few hours' illness, a fortnight after having menstruated. He detailed the cases as follows:—

ULCER OF THE STOMACH: PERFORATION.

October 10th, 1847. Mr. Russell was called to see, with Dr. Melson, a servant, middle aged, mother of two children, to whom Dr. Melson had been called early in the day; she had often been a free patient of Dr. Melson's, suffering from dyspepsia and gastrodynia. In the morning Dr. Melson had found her with great pain in the belly, and vomiting; abdomen much swollen and extremely tender; she had not been able to micturate. He ordered two grains of opium, four grains of calomel, and a prussic acid mixture. In the evening Dr. Melson and Mr. Russell found her in bed on her back; the vomiting had ceased, but she was in great pain; her pulse quick, but not feeble; tongue dry; abdomen very tympanitic, and extremely tender; bladder empty. At 10 p.m. she was much the same, the abdominal tenderness had increased, but the pulse was firm. She died between one and two in the night.

Sectio Cadaveris, forty hours after death.—The body was well nourished, and had a healthy aspect; the abdomen greatly distended; a large chamber-pot was quite filled with yellowish fluid, contained in the abdomen, in which were floating globules of castor oil, which she had taken of her own accord immediately before her death; the surface of the bowels was vascular, and thinly coated with recent lymph; the intestines perfectly healthy throughout, and without a trace of ulceration; stomach appeared healthy externally, but on being opened, a round ulcer, large enough to allow a lead pencil to pass, was found in the upper part of the anterior wall, to the left of the middle line; it was clean cut, and a few fine shreds of cellular tissue still stretched across it. The mucous membrane of the organ I thought rather soft, as it did not tear off in strips, and the muscular coat was hypertrophied; the stomach offered unusual resistance to the scissors, and the middle coat was seen whiter and thicker than usual. There was a fibrous tumour, about the size of a large walnut, in the wall of the uterus.

The subject of the second case was a servant girl; she was only ill for a few hours. She had been subject to femoral hernia of the right side, but it was reducible at the time of her decease. An inquest was held on the body on account of the suddenness of the death.

The abdomen was distended with about three quarts of yellowish fluid; the surface of the intestine covered with recent lymph. The stomach was perforated by a round ulcer, about the size, internally, of the end of the little finger, externally, somewhat smaller, in the upper and left part of the anterior wall; the perforation was situated in a very thickened portion of the coats of the organ, and was about the size of a crown-piece. The stomach afforded unusual resistance to the scissors when cut; intestines healthy; hernia reduced; the liver presented a peculiar sodden appearance.

This specimen was sent to Mr. Russell by Mr. Percival, who opened the body, but could not learn more of the history of the case.

RUPTURE OF THE FALLOPIAN TUBE.

The following was the history of the ruptured Fallopian tube:—

Mr. Russell was sent for hastily at half-past two, p.m., to a young lady, about twenty-five, married four months. He found her in bed, in a state of great collapse; skin

cold, pale, and bloodless, and she complained of intense pain in her bowels. She had been sick, and had had three purging stools; abdomen very tympanitic and tender. She had been in this state for two hours, without having been able to procure advice. He could obtain but little information from herself as to her previous state, and could not trace her having ever suffered any local pain. She did not think herself in the family-way, as she had menstruated a fortnight previously, and had not experienced any symptom which would lead her to suppose herself pregnant. Mr. Russell had little doubt that some perforation existed, and would have supposed it seated in the bowels, but that her bowels had been moved, which he never knew to occur in such cases. She referred her pain chiefly to the præcordia. Her pulse was scarcely perceptible. Fomentations, opium, and ammonia, as she objected to brandy, were ordered. She somewhat recovered, but soon sank again, and died in great pain early on the following morning.

Sectio Cadaveris.—On opening the abdomen, a quantity of thin fluid, tinged with blood, flowed out. At the lower part of the abdomen was a large clot, the size of a saucer, and on removing this the left Fallopian tube was found ruptured. The rupture was situated near the junction of the middle and inner third of the tube; the ruptured portion was distended by a mass of fibrin, about the size of a large hazel nut, in which, however, no ovum was discoverable; the wall of the distended portion was very thin. The uterus was enlarged, and contained a deposit of decidua.

SINGULAR CASE OF TWINS.

Mr. Hill presented a blighted fœtus, apparently about the fifth month, which was born thirty-six hours before a fully-developed healthy fœtus. He gave the following report of the case:—

I was requested to see Mrs. J., a middle-aged woman, the mother of several children, the gentleman in attendance thinking it was the shoulder that presented; but upon a more careful examination, (the labour having proceeded somewhat,) we discovered that it was the head of a child, apparently about four months. The membranes were ruptured, and the child expelled. The labour pains then subsided, and it was about thirty-six hours after that a second child of the ordinary size, and alive, was born. The placenta was double, and did not differ from that of an ordinary twin case.

Mr. Heeley exhibited some serum taken from a hydrocele.

THE BENEVOLENT FUND.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Six months having elapsed since our last Anniversary at Derby, and during this period a considerable effort having been made to revive and extend the resources of our Benevolent Fund, and to urge its claims more especially and individually upon every member of our Association, it becomes desirable to pass in brief review the results of this experiment,—its measure of success,—the objections which have been urged,—the reasons for not subscribing,—and the suggestions which have been made for the future government and more extended efficiency of the Fund.

I. Let me record my deepest thankfulness and most heartfelt gratitude, for the many, very many, instances of unlooked for kindness and encouragement which I have received; and for the many exhortations which have been given me to proceed in the most strenuous efforts to extend the resources of the Fund. Let me also record my warmest thanks to the very numerous donors and subscribers, who have most cheerfully given their cash in favour of this object;—to those who have cheered me with the hope of future support, when brighter days dawned upon their own path;—to those who, feeling themselves unable to *give*, have still afforded the moral strength of their support and approbation;—to those who have given me the aid of their thanks, and the benefit of their influence, and the strength of their sympathy, and the stimulus of their cheering "forward," and the advantage of their experience and suggestions.

There is another class to whom my cordial thanks are due,—to *those*, and especially to *those ladies*, who have aided the Fund by their disinterested exertions on its behalf. Enough has been done in this way to show how much more might be done, if individuals could be persuaded to make this an object of attention among their non-professional friends, and patients, and acquaintance. The experiment has succeeded in every instance in which it has been *fairly* tried; the instances of polite refusal have been rare; the case of a brusque denial has not existed; and experience has clearly shewn, that if this plan were carried out with zeal, and energy, and discretion, an abundant fund would be at once created. There are those who are very sensitive upon the point of asking a favour of their friends, and I quite admit the validity of the objection where the favour is asked for oneself: but this is entirely obviated, when the favour asked is not for ourselves, but for others;—for others in distress, penury, sickness, and infirmity, or destitution;—when, in fact, the favour asked is wholly unselfish, perfectly disinterested, and clothed in the consecrated garb of heaven-born charity. To feel for others' woe, and to endeavour to relieve it, can only evolve the best and highest sensibilities of our nature, and return in blessings, and increased estimation, upon the head of the applicant.

II. But there has been a class, though a very small one, of objectors against the principle of the Benevolent Fund, and their objections resolve themselves into two distinct propositions:—It is degrading to a society created for literary and scientific purposes, to have attached to it a fund for the relief of the unfortunate; and there ought to be no such persons, since every man should have been provident enough to secure himself from the hour of misfortune, by prudence, economy, and foresight.

First, it is degrading to the Association! Degrading indeed, to place before it as one of its important objects, *the good of others!* the very highest purpose for which man was born into the world, and that which assimilates him most closely to the Divine author, and most perfect pattern of benevolence! The *first*, the only object of the Association is, to do good to others upon the most extended scale. The only objection which is

ever urged against it is, that it has not done all the good which it might have done; and its highest aspiration is to do more good. In what way, then, can it be degrading, to look around among the unfortunate members of the profession, and to endeavour to relieve their sorrows and their miseries, as well as the sickness of the public? Degrading, indeed, is it to the profession, that such sorrows should exist unrelieved! Degrading is it, that in a profession where charity is said to abound, there should flow so little of its kindliness towards the channel of fraternal love; and that, while other and more prominent charitable institutions are supported, family trials and destitution should be superciliously overlooked. If there be degradation in this pursuit, we cannot have too much of it; and if this object be counted unworthy, then indeed may we say, "Evil, be thou my good!"

But secondly, the *necessity* for such charity and benevolence *ought not to exist.* But it does exist: facts shew it. Every days's experience reveals the depths of hidden misery; and it would perhaps be sufficient to reply, that it does exist, and therefore, that an institution for its relief is absolutely required. But I would not rest in this simple answer, because I would show that in the present state of our profession it must necessarily exist, and that no prudence nor foresight can avert it. It is not for those on whom the sun of prosperity has shed its cheering rays all the way through life, to infer that others have been, or could have been, equally prosperous and successful. It is a well-known fact, that taking the entire number of medical persons in this kingdom, there are comparatively *few* who can live, and maintain, and educate their families on their *professional* income. If so, there must be a large number of men, who have spent their little all before they have obtained an adequate income from their practice, and consequently, who have no private income:—there must be many to whom nature has not been bountiful in point of talent;—there must be also some, who, possessing talents and information, are yet wanting in the manner which is necessary to make their acquisitions available for their support;—there must be others who have commenced life with cheering prospects, but in whom ill-health, or accident, or blindness, or some one of the numerous ills which flesh is heir to, has disabled from obtaining the required income. There must be some whom the loss of property from one of the casualties of life has left destitute;—there must be those who have been utterly disabled by insanity, or bodily infirmity; and there must be others who have struggled on upon an insufficient income,—have educated their families, and have died, and left those families reduced to beggary;—or who themselves have lived till they were past work, and have known what it has been to suffer from cruel want: and all these are to be found, not among the idle, and improvident, and dissolute, but among those who have been remarked for industry, prudence, care, and the most praiseworthy economy—a rigid economy, practiced in secret to an extent that none but such sufferers can comprehend. Now, each one of these classes is taken from the life, in my own circle of knowledge, and therefore their existence cannot be denied.

But it is said, they *ought not to exist,*—men should not marry till they can support a wife; they should insure their lives before they marry; they should provide annuities for themselves and their wives, or the survivor of them;—they should purchase deferred annuities to commence at 60 or 65, when they are becoming disabled from active duty;—they should endow each child as it is born; and they should avail themselves of every means of providing against casualties and misfortunes, which the progress of knowledge, a commercial country, and a speculating age have afforded them. Most thoroughly do I approve of such provision; much do I deplore that such a professional society upon the mutual principle does not exist among us,—one that would take in every kind of risk arising from professional contingencies. But supposing such a society in existence, let as see how this principle would operate in a great many cases. A young man settles in life, and obtains a tolerable income,—enough for him to spare a certain sum annually to insure his life. The insurance is effected, and he now considers that were he married, he should not only add to his comforts, but probably also to his professional success, and he sees that he can now marry prudently, while he hopes that the consequent addition to his professional income will be sufficient to meet the expenses of an increasing family; and hope, that ever buoyant passion and principle, leads him to look forward with cheerfulness, and even with sanguine expectation. Perhaps he has provided an annuity for an annual payment; perhaps he has endowed his early children; he has done all that he could to provide for futurity. But he has a large family; and now first comes a cloud over his horizon, in the sickness of his wife or children, or himself; his expenses are necessarily large,—and for the first time his income has not equalled his expenditure; his bills are not all paid up, and his energies are chilled by anxiety and apprehension. But he manfully struggles on, and hopes that a year or two may put him straight. And now, perhaps, some younger, active, taking competitor trenches upon his resources; every year his expenditure becomes larger, while his income does not increase—perhaps is lessened,—at all events is subjected to the most trying fluctuations; the sicknesses of himself, or his wife, or children, are repeated,—other unavoidable losses fall upon him,—the expenses of education become heavier every year,—difficulties increase,—credit lessens,—his brain is maddened by the apprehension of losing his position in society,—he is attacked by paralysis, and never earns another shilling: or he struggles on, and tries to maintain his insurance and annuity premiums; by-and-by this becomes impossible, and they drop, or he is obliged to sell them for present cash, to obviate present difficulties; misfortunes accumulate upon him, and he and his wife and children are left destitute. And how could this be avoided? It is not true therefore that such cases ought not to exist, but it is true that they must exist, so long as misfortune on the one hand, and sickness,

and losses, and poverty, are to be found, and are only to be relieved by a *selfish world.* Hence the necessity for a thoroughly unselfish and purely Benevolent Fund like our own, which will relieve distress, *because it is distress*, and not *because it has been qualified for relief*, by a certain number of years' subscription to any one of those admirable funds, which exist in various localities through the country, but which do not, and cannot, relieve the misery contemplated, as the object of attention to the Benevolent Fund.

III. It now becomes us to take review of the reasons given for not subscribing to this Fund. These are—

a. A subscription to one of the local and admirable institutions above mentioned. This might be a sufficient reason, if the objects and constitution of the two institutions were *identical*, instead of being precisely the contrary. The one relieves those, who by a certain number of subscriptions have entitled themselves to aid,—the other succours those who have been unable to make such provision;—the one relieves distress within a certain boundary,—the other relieves it wherever it may be found;—the one ministers to destitution, which has a claim upon its funds,—the other stretches out the hand of charity towards misery, which has no claim for relief, and which has no other source of succour. This fact has been frequently shown in the history of the Benevolent Fund, because it has oftentimes relieved the most abject distress, (and has already done so this year,) within the circle of very rich amicable societies. While then it is right to support these very valuable institutions, such support forms no sufficient ground for not subscribing also to the funds of a kindred, but purely benevolent, institution; on the contrary, the very fact of subscribing to an amicable fund, for the relief of sorrow in a small circle of membership, should inspire the heart with the desire of aiding also the good cause, in the larger circle of unprovided wretchedness.

b. Subscriptions to the General Medical Annuity Fund. The plan abstractedly of a *mutual* annuity society is a very valuable one, and may be productive of admirable results, provided that its calculations be correct,—provided that it be taken up and carried on, not as a matter of charity, which it is not, but as a matter of right, and of business;—provided that it be founded apon a due appreciation of the value of professional life;—provided that the age of entering such a fund be an early one, or that an equalizing payment in one sum be paid on entrance for every year beyond the early period of life upon which the first calculation is made;—provided that the annual sum paid be sufficient to procure an annuity of a *tolerable* amount, either after a certain period of life, or for a widow upon death;—provided that the sum so paid be regulated by the ages of the subscribers, and that an equalizing payment be made upon marriage for the difference between the two ages of husband and wife;—and, provided that the calculations shall have been carefully examined, and certified to be correct. Yet such an institution, however valuable in itself, is one which provides for *its members*, and equally leaves upon each individual the unselfish duty of providing for him who is ready to perish, and has no other hand outstretched to save him from destruction.

c. Inability to subscribe on the ground of the inadequacy of personal resources. Truly, most truly, do I respect this reason, where it really exists; and deeply do I appreciate the good wishes and moral support from this class of unwilling recusants. Obviously, we must be just before we are generous, and there is no charity in giving away the money which belongs to others to whom we are indebted. But then the essential life of charity consists in self-denial,—and the cases must be rare indeed, where the abnegation of self in some little luxury would not easily, most easily, produce the required five shillings, or ten shillings, or even twenty shillings a year for so valuable an object; and although I would by no means fix five shillings a year as the maximum of ordinary subscription, yet five shillings a year from each one of our members would produce an income of £500 annually.

d. But there are really those who cannot by any effort of economy and self-denial, justly spare even five shillings a year for such an object. Admitted: but if so, how strong an argument does this afford in favour of the Benevolent Fund; for if there exist such a class of persons, it is obvious that they do not possess the means of subscribing to any of the local institutions above mentioned, which require for membership more than four times the sum specified; and it is equally obvious that the first great misfortune,—the first severe illness to themselves or their family, or the first serious pecuniary loss, must throw them into temporary embarrassment,—and if repeated, must soon place them as claimants upon the Benevolent Fund—the only fund which can relieve them.

e "A fixed and equal payment should be made towards this object by an addition to the annual subscription of members." This plan has been several times *mooted*, but it has failed of meeting with acceptance; and deservedly, because from the moment that the offering of charity is doled out from a compulsory fund it has ceased to be blessed at all,—the poisonous exhalations of taxation have encircled it,—the growth of the benevolent affections has been stunted,—the pure and evergreen shoots of charity have become withered,—and the institution is doomed to a lingering sickly existence, and early death.

f. "The Association has not done all that it might and ought to have done; it has spent large sums upon producing second rate matter; and until it expends its large income better, we cannot subscribe." This is equivalent to saying that the Association has not done what it might have done with its large income; and therefore, though the Benevolent Fund has done much with its small income, we will not furnish it with the means of doing more.

It is not for me, Sir, to enter the lists in defence of the Association. Perhaps it has not effected all that it might have done, and of what human institution may not this be equally predicated? I am also free to confess that at one time its Journal was cramped,—and it was also unfortunate in sustaining some

heavy pecuniary losses. But it has shown its inherent vigour in its volumes of "Transactions," some of which contain papers of inestimable value; and the pages of the Journal now proclaim something like the power and energy of manhood; and its Council Fund is in operation, and must produce good results; and many of its members are awaking from the lethargy which has oppressed their manhood; and all these things show that on this ground, there is no real excuse—an excuse by the bye, remarkably put forward by those who have contributed nothing to the efficiency of the institution. Besides, admitting all that is said against the society to be true, (which, however, I distinctly deny,) what ground does it give for not subscribing to the Benevolent Fund, which *has done* all it could, as far as it was furnished with the means.

g. There is, however, a considerable class, who have not subscribed, and yet have not stated their grounds of non-compliance with the invitation sent them. Now, since it is impossible to suspect any one of our members of the intentional discourtesy of not replying to a written note of application, it must follow, that they who have been silent, have probably been influenced by one of the above-mentioned motives, which they have not liked to state; or that they have been intending to respond to the application in a practical manner, when they paid their subscription to the general Association; or far, more probably, that it has been forgotten. In either case, let me from such, request a serious, impartial, and conscientious review of the grounds of objection to subscription, and I venture to predict an accession to our funds; and if, as I believe, the great evil has been forgetfulness, let me earnestly entreat the extermination of this enemy to all good; and let me close, in the words of the wise man, "Whatsoever thine hand findeth to do, do it with thy might," for "the night cometh when no man can work."

IV. It remains for me to notice some suggestions which have been made for the advancement of the society, and the extension of its agencies; for all these I beg to say that I feel personally under the deepest obligation to the suggestors. Some of these hints for giving greater publicity to the institution, have been most thankfully received, and shall be attended to next year. Others, such for instance as the establishment of a home for superannuated medical men,—a confederation of *sœurs de la charité* from his daughters,—an institution for temporary refuge,—a depôt for travelling companions,—a sanatorium,—a lunatic asylum, &c., &c., are not yet within our reach. Happy shall we be to embrace such-like suggestions when in our power; at present they would only cripple our resources. At present our two-fold object must be, to obtain a larger available income for the relief of present distress, and the carrying up of our donation fund to such a sum as shall enable us to bring it into operation. Both these objects have been partly accomplished. During the last six months a considerable amount of donations has been received, and there has been a considerable accession of annual subscribers; both, however, fall far short of what is needful, and require continued exertion, and I doubt not the result will be all that we can wish. Towards the accomplishment of this end, the following suggestions, most of them from valued correspondents, will be useful, though, after all, the secret of success consists in individual energy, individual subscription, and individual efforts, to raise something among *non-professional friends*:—

1. It has been suggested that each subscriber of the present year should furnish an additional subscriber for the next year.

2. That the married ladies should undertake to raise small contributions among their friends and acquaintance, a plan which in some instances has been very successfully acted upon.

3. That the President of each of the Branches of the Association shall give his active support to the Fund.

4. That a Sub-Committee be appointed from the Council of each local Branch, and be requested to co-operate with the President in collecting donations and subscriptions, to to be forwarded to the general Treasurer.

5. That every application for relief from such district should be made through the said local Committee and President.

6. That the several sums, with the donors names, be read at each annual local dinner, when the toast of the Benevolent Fund is given.

7. That the object of the Benevolent Fund should on all occasions form the subject of a toast after dinner; and that where no local objection existed, (to be determined solely by the President,) it should be coupled with the opportunity of making that offering from the heart, which might be prompted by a recollection of the advantages and interest of the scientific meetings just over,—by a grateful emotion for the comforts and benefits of the social scene then commemorating, and by the consequent earnest desire to irradiate the gloom of that cheerless garret of misery which is unenlightened by social pleasure, and uncheered by sufficient for the day. Such a plan, in kind and Christian minds, would only add to the light of social enjoyment, the peculiar halo of moral health.

These, Sir, form a summary of the suggestions of many of my correspondents, and with them I close my communication, remaining,

Yours sincerely,

W. NEWNHAM,

Honorary Secretary and Treasurer.

General Retrospect.

PATHOLOGICAL CHEMISTRY.

ON THE DISCOVERY OF UREA IN PERSPIRATON.

By Professor Landerer, Athens.

The quantity and condition of the secreted urine depends, as already known, on the quantity and quality of the fluid ingesta, and the greater or less transpiration. The urine consequently becomes more concentrated during summer in warm countries, than in

winter, and this may be discovered by the increase of the specific gravity. The increased quantity of salts in the urine, dependent on this concentration, is probably the cause of the numerous calculous affections in warm countries; while the vegetable nourishment and use of fruits, especially grapes, is probably the cause of the rarity of sand and gravel. Almost all strangers in southern countries become affected with a peculiar exanthema, from the irritating effect produced on the mucous and sebaceous follicles, by a portion of the solid contents of the urine finding their way to the skin. One author, to convince himself of the presence of these salts, collected the washings of flannels and shirts—a fluid possessing a striking colour of perspiration, of a very salt taste, and slightly acid properties. This fluid, evaporated to a yellow syrup, deposited after exposure to cold some days, a granular mass of phosphates; the remainder, digested in alcohol, formed a yellow solution, which, on spontaneous evaporation, left a substance possessing a strong odour of perspiration, and a sweet taste. This, dissolved in water, and decomposed by diluted oxalic acid, deposited after thirty-six hours, a precipitate of small crystals of oxalate of urea. To make the presence of urea more evident, these crystals were dissolved in water, and the solution decomposed by carbonate of lime, to separate the oxalic acid from the urea. The supernatant fluid was then evaporated to dryness, and the residue dissolved in boiling alcohol. This was again evaporated, and a few drops of nitric acid added; from this, after cooling in a refrigeratory, crystals of a silky lustre were deposited, which, separated from the mother water, posessed a cooling, slightly acid taste, and crackled in the fire. From all these operations, our author believes that urea was present in the perspirations, and that muriate of soda, traces of sulphates, acetates, and lactates, osmazome, and a clear substance easily soluble in æther, were also present.—*Heller's Archiv für Chemie und Mikroskopie*. Jahrgang, 1847. Heft, 3.

METHOD OF DISCOVERING IODINE IN THE URINE.

Boil thirty-two ounces of urine down to one, soak a strip of starched paper in it, then rub over the paper a glass rod dipped in nitric acid; a blue colour results if iodine be present.—*Annales de Thérapeutiques*, Nov., 1847.

SURGERY.

COMPARATIVE MORTALITY FROM PHLEBITIS AND SECONDARY HÆMORRHAGE, AFTER THE FLAP AND CIRCULAR OPERATIONS.

Mr. Fenwick states that out of 165 flap-operations reported by Dr. M'Hardy, twelve cases of phlebitis occurred, or 1 in 13.75; whilst of 199 circular, only nine, or 1 in 22.11 were so affected. Again, Mr. Alcock states, that out of 87 circular operations, ten died of phlebitis, or 1 in 8.7; whilst of 24 flap-operations six perished, or 1 in 4. Taking, then, the general amount of death as caused by this disease, the advantage is vastly in favour of the circular operation.

The liability to secondary hæmorrhage is about equal. Thus, according to Alcock, in flap-amputations, it occurred once in 12.68 cases; in the circular once in 13.26.

Mr. Fenwick further remarks:—The question which it is necessary to settle before determining which form of amputation is to be performed in any particular case, appears to be, whether the advantages of a better stump and a quicker recovery outweigh the increased liability to phlebitis. In amputations for diseased joints, in which phlebitis and secondary inflammations are of comparatively rare occurrence, and in which necrosis and conical stumps are most likely to take place, the flap-operation appears in most cases to be indicated, especially if the arm be the part to be operated upon, and the patient be young. On the contrary, in traumatic operations of the lower extremity, the circular operation would seem the most advisable, as in such cases plenty of covering can always be obtained for the ends of the bones, whilst we at the same time subject the patient to a less risk of phlebitis than by the other method.—*Monthly Journal*, Dec., 1847.

URETHRO-PERINEAL CALCULUS.

Tumours in the perineum, formed by the presence of calculous concretions, have been at various times placed on record,—one quite recently, by Dr. Barker, of Bedford, ("Transactions of the Provincial Medical and Surgical Association," New Series, vol. III.,) is an interesting instance in point. The following case, though analogous, differs in some respects, but principally in the fact that the prostate gland is not implicated, and that the stone is single instead of multiple:—

In March, 1840, M. Payen was consulted in the case of a man, aged 54, who was the subject of a tumour in the perineum. It appears that he had been cut for stone at the age of five years, and had since been perfectly well, with the exception of a small perineal fistula. This gave him but little annoyance, and he therefore paid no attention to the state of the parts, until he discovered a swelling above the orifice of the fistula, which gradually increased in size, until it interfered with his walking, as well as micturition.

On examination, a large tumour was discovered in the perineum, which pushed the scrotum forwards, and at the same time separated the testicles. It was hard and resistant, and by passing a probe into the fistulous opening, it was clearly ascertained to be of a calculous nature. As the patient was losing flesh, and was in fact suffering from incomplete retention of urine, it was determined to remove the cause of the complaint.

The patient was accordingly placed as in the operation for stone, and a director being introduced into the fistulous opening, the perineum was incised above and below to an extent which would allow of the removal of the stone. This being accomplished, the stone was lifted out of its bed, and was easily extracted. It proved to be a single calculus of a pyriform shape, and so hard, that it did not break by falling on the ground. The cavity whence it was removed, would contain a child's doubled fist. On further examination, this cavity was found to be a cyst, formed in the cellular tissue of the perineum, but communicating with the urethra, as well as the fistula. The weight of the

stone was twenty-two grammes, (five drachms and a half nearly.)

The after progress of this case was, that the canal of the urethra could not be re-established, the patient remaining with a large permanent perineal fistula.—*Encyclogr. des Sciences Médicales*, Aout, 1847.

RUPTURE OF THE BLADDER FROM INJURY: RECOVERY.

The annexed case is reported by Mr. Syme, and is considered also by the editor of the *Monthly Journal* as unique, but erroneously so, as a still more extraordinary case was recently narrated by Mr. Chaldecott. (See *Provincial Journal*, 1846, p. 333, and *Half-yearly Abstract*, vol. 4, p. 64.) It is, however, perhaps the second on record, and is, therefore, worthy of further publicity.

On the evening of July 5th, Mr. Syme was requested to visit a youth, who having attempted to leap over a railing, had fallen forwards, and violently struck the abdomen against a post. He immediately complained of great pain, and the abdomen became distended. A catheter introduced, allowed the passage of about four ounces of bloody urine. There were all the signs of ruptured bladder, with great collapse. Leeches and fomentations were applied, and an opiate prescribed. On the following day the abdominal pains and swelling were increased, with dulness on percussion below the umbilicus, and tympanites above. The next day the abdomen was still further distended, and there was œdema of the posterior parts, from the chest down to the thighs. The catheter was introduced twice, and drew off bloody urine. On the following day the œdema had increased to a great extent, and the breathing was much embarrassed. Below the umbilicus there was now obscure fluctuation, which induced Mr. Syme to make an incision into the linea alba. After cutting through a thick mass of condensed tissue, a stream of fluid passed out, which was distinctly urinous, and considerable relief was experienced. On the next day the pulse had fallen to 100. On the 11th, some fever, which abated by making a freer opening in the abdomen. On the 26th a slough appeared at the orifice, which being removed proved to be dead cellular tissue, coated with deposit from the urine. Mr. Syme then passed his finger into the wound and felt a laceration in the position of the bladder, uncovered by peritoneum. On the 5th of August the patient passed urine per vias naturales, and in another fortnight was well.—*Monthly Journal*, Jan., 1848.

[This case, though remarkable, is less so than that reported by M. Chaldecott, as in the latter the urine was evidently effused into the peritoneal cavity. In both cases the patient was saved by the judicious treatment adopted.]

ANIMAL LIGATURES.

Mr. Wragg states that he has been in the habit of using these ligatures for upwards of ten years. In the course of this period he has tied the arteries of the hand, fore-arm, leg, and thigh, and believes that the knot has always been removed by absorption. The ligature used has been the fibres of the sinew of the deer, twisted to the requisite strength. The sinew is first dried and the fibres are then obtained by tearing them out from the middle towards the extremities. When used the ends are cut off close to the knot.—*Southern Journal of Medicine*, Sept., 1847.

MANCHESTER MEDICO-ETHICAL ASSOCIATION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I beg to inform you, that at a meeting of the Committee of the Medico-Ethical Association, held on the 3rd instant, the following resolutions were unanimously adopted, and which I shall be obliged by your inserting in the next number of your Journal.

I am, Sir,

Your obedient servant,

RICHARD ALLEN.

Oxford Road, Manchester,
February 7, 1848.

Resolved,—

"That since the course adopted by the Life Insurance Companies, with regard to the payment of fees for medical certificates, varies in different offices, and since the profession is greatly dissatisfied at the difficulty of obtaining remuneration when acting as medical referees of applicants for insurance, the Committee are desirous that an effort be made to effect such a settlement of the question, as shall be advantageous to all parties interested."

Resolved,—

"That a sub-Committee, consisting of three members and the Secretary, be appointed to frame plans calculated to carry out the object of the first resolution, and also to prepare a memorial, which shall embody their proposals, and recommend them to the equitable consideration of the Insurance Companies. That the report of the sub-Committee be laid before the general Committee as early as possible."

In accordance with the last resolution, the sub-Committee was appointed.

SANITARY STATE OF RURAL DISTRICTS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

The sanitary movement which progresses so satisfactorily in our larger communities is unhappily too limited in its projected application. The evils dependent upon former inattention to sanitary measures are in cities and large towns most marked, on account of the aggregation there of the victims of over-crowding, filth, and inefficient drainage and ventilation. But it is a fact, as yet, comparatively unknown or unheeded, that villages also experience an amount of depopulation which wholesome legal enactments would tend greatly to diminish. It is only on account of its widely spread diffusion that the extent of preventible deaths in rural districts has not received the attention it requires at the hands of sanitary reformers; for, were the isolated cases collected into one whole, they would be found to present an alarming proportion to the general list of mortality.

Impressed with this conviction, I have resolved to appeal (which I do most earnestly,) to my brother country practitioners, and especially to Union medical officers, (for to them must the evils complained of, by virtue of office, be most apparent, and most important,) for such early information as shall enable me to make a statistical report of the sanitary condition of our villages and smaller towns, which, if only an approximation to the truth, will show the necessity of extending to such places the benefits derivable from sanitary legislation.

Appended hereunto is a tabular list of queries proposed; it is left unincumbered with many details which I should have been pleased to add, but that it is desirable that the report should embrace the statistical data of as large a proportion of the rural districts as possible. The professional duties of the class of practitioners of whom I request information, afford them little time for extra-official avocations; for which reason I would also limit my enquiries to the last five years, during which fever has been unusually prevalent.

Trusting that you will insert the above appeal, and further its object by your sanction, in the next number of your Journal,

I am, Sir,
Your obedient servant,
JOHN MOORE, M.R.C.S., Eng.

Bourton-on-the-Water, Gloucestershire,
January 25, 1848.

Statistics of Fever in Rural Districts.

Year.	Names of Villages or non-corporate Towns, and County in which they are situate.	Population.	No. of Cases.	Mortality.	Causes which have appeared to extend the disease or to increase its fatality.

MEDICAL ETHICS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

When I forwarded to you my remarks upon the bye-laws of the Manchester Medico-Ethical Association, to which you so kindly gave insertion, in your Journal of the 29th of December last, my only object was to point out, so far as my own experience went, the inapplicability of some of those bye-laws to the existing state of society. I discovered in those bye-laws the elements of good, and therefore took the trouble to interest myself so far about them. I gave the Medico-Ethical Association credit for a desire to elevate the moral social state of the profession, and in consequence, did anticipate a very different course from that adopted by the Honorary Secretary of that Association, in reply to my observations. I had expected that he, or some member of that body, would have defended the objectionable clauses to which I referred, or have had the candour to acknowledge their inapplicability to practice; but neither of these plain courses has been adopted in the reply to which I refer. It does intimate that all communications must be authenticated by the signature of the author. Now, in the published list of bye-laws, I recognize only measures, *not men.* I object to certain principles there laid down, and give my reasons for so doing, and hoped to be met by reason on the other side. I shall be happy to acknowledge my error, if the Association or its Secretary, or any one else, can prove that my views are erroneous; but of what importance is my name? What has it to do with the subject matter of these bye-laws? Argument alone can convince the profession of their propriety; vituperation but shows the weakness of a cause. In your Journal I stated my own case without distortion or exaggeration, and gladly would have been on terms of friendship with my medical brethren; but in me they saw but a stranger, and so long as I was content to be a physician *without a patient,* they kindly took no notice of me or my proceedings. They knew I was guiltless of harm to their pockets; but when in self defence I commenced to practise as a general practitioner, then they met, combined, and resolved unanimously not to meet me in consultation, on the ground that being a physician, and consequently one over whom they had hoped to preserve and *employ* the power never to call in, I had dared to enter the lists as one of themselves, and had therefore been guilty of "unprofessional conduct." If the Honorary Secretary of the Manchester Medico-Ethical Association will be kind enough to point out, under these circumstances, why *I* am to be taunted with—"in no instance having visited a patient as the officiating friend" of my medical brethren, I shall thank him for the information. I came, as I before stated, a total stranger,—purchased a fictitious medical practice,—found I had thrown my money away,—turned my knowledge of my profession to the legitimate object of practising it amongst the poor, —paid no fulsome court to the wealthy. *They called on me.* I succeeded in practice in despite of combined opposition. This is my crime,—this my "vaunted systematic violation of principles!" What principles?

With all deference to Mr. Allen's opinion, I submit that I am not therefore disqualified to judge of "medical etiquette," when based on common sense; but I freely admit that any form of "etiquette" which would nullify the *tested* superiority of one practitioner over another, render mind and a lengthened application to the study of a noble, arduous profession, (when coupled with superior acquirments obtained from learned bodies of examiners in the tangible shape of honourable degrees, taken out at the sacrifice of much time, health, and money,) to rank as so much trash in the after-pursuit of fame and emolument, and would forbid the possessor from using these manifest and hard-earned advantages for the good of his fellow-man and himself, without the previous sanction of the former medical attendant, (who is perhaps less than half educated in his profession,) harmonises

badly with my ideas of justice, of reason, and of common sense. In what other profession is this deference paid to a less qualified fellow-practitioner? Let a man be on trial for his life, (which all patients are,) and will Mr. Allen contend that a member of the bar, of admitted talent, will decline to defend the accused, and suffer him to undergo perhaps the penalty of death, because he was unfortunate enough to have had some ignorant pettifogger for his counsel in the early stages of the law proceedings? And does he suppose that the Attorney-General (for instance,) would think it necessary to ask permission of the said pettifogger, and afterwards feel bound to take him into his councils "for etiquette sake," when requested by a client to save him from death and ignorance?

In a word, is all honest rivalry and competition to be excluded from the profession of medicine alone?—are patients only to be bought and sold or transferred by inheritance?—and is the practitioner, "authorized by act of Parliament to practise," to hold, "as his own," possession of the bodies of all those he buys, or inherits, so long as life is in them? for such indeed, appears to me, to be the spirit of those bye-laws, to which I objected. If such have been the spirit of the "etiquette of the profession," let us in the name of all that is decent, lend our utmost aid not to the perpetuation of our disgrace, but with all possible dispatch, to rase with the ground the very traces of this barbarous refinement, clumsily disguised under the name of "Professional etiquette."

I have the honour to be, Sir,

Your very obedient servant,

H. B. B.

Medical Intelligence.

HOUSE OF COMMONS.

Medical Registration.

On Monday, February 14th, Mr. Wakley moved the nomination of a Select Committee on medical registration and medical law amendment. The following gentlemen were appointed on the Committee:—Mr. Wakley, Sir James Graham, Mr. Rutherford, Mr. George Hamilton, Lord Robert Grosvenor, Sir Henry Halford, Colonel Mure, Sir Robert Harry Inglis, Mr. M'Gregor, Mr. Walter, Mr. French, Sir Thomas Birch, Mr. Osborne, Mr. W. S. Lacelles, and Mr. Grogan.

APPOINTMENTS.

Joseph Dickenson, M.D., has been unanimously elected Physician to the Liverpool Infirmary, in the room of Dr. Duncan, resigned.

Allen Thompson, M.D., Professor of Physiology in the University of Edinburgh, has been appointed Professor of Anatomy in the University of Glasgow, in the room of Dr. Jeffray, deceased.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, February 11th:—H. Gray, C. J. Evans, C. A. Lee, T. Maurilyan, C. Crowdy, J. S. Burd, J. Drew, J. W. Tripe, F. Manby, R. Mason.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, February 3rd:—Charles Edward Prior, Worcestershire; Harry Gardner, Somerset; William Richard Black, Lincolnshire; William James Blyth, Abergavenny.

Thursday, February 10th:—James Reed, Pontypool; Robert White.

OBITUARY.

Died, January 18th, at Caheragh, Skibbereen, aged 35, of fever, James Brady, M.D., Medical Officer of the Fever Hospital.

January 26th, at Killaloe, County Clare, of Influenza, George Purdon, M.D., Medical Attendant of the Dispensary, and Surgeon on half-pay of the 22nd foot.

January 31st, at Farningham, aged 47, Edward John Ryan, Esq., Surgeon.

February 4th, in Leith Walk, Edinburgh, Matthew Buchan, jun., M.D.

February 5th, at Dalkeith, of fever, John Hunter, M.D.

February 7th, at Falmouth, aged 30, William Paterson Banks, M.D., Surgeon, R.N.

February 9th, of fever, Patrick J. Finnegan, M.D., Physician to the Dundalk Dispensary, to which Institution he had been attached only a few weeks.

February 11th, at Glasgow, aged 66, R. Perry, M.D.

Lately, at Ballymoney, of fever, John Reynolds, Esq., Surgeon to the Ballymoney Dispensary.

BOOKS RECEIVED.

The Microscopic Anatomy of the Human Body in Health and Disease. Part XII. By Arthur Hill Hassall, F.L.S., &c. London: Highley. 1848.

A Disquisition on Pestilential Cholera; being an Attempt to explain its Phenomena, Nature, Cause, Prevention, and Treatment, by Reference to an Extrinsic Fungous Origin. By Charles Cowdell, M.B., M.R.C.S. London: Highley. 1848. 8vo. pp. 210.

British Cholera, its Nature and Causes, considered in Connexion with Sanitary Improvement, and in Comparison with Asiatic Cholera. By Spencer Thomson, M.D., &c. London: Churchill. 1848. Post 8vo. pp. 110.

Sanitary Reform and Agricultural Improvement; &c., &c. By Charles F. Ellerman, Esq. London: Peirce and Hyde. 1848. 8vo. pp. 70.

TO CORRESPONDENTS.

Communications have been received from Mr. F. Buckell; Mr. Page; Mr. Crompton; Mr. R. Ley; Mr. R. U. West.

A Subscriber.—Any person, whether M.D., or not, may prescribe without fear of molestation in the present state of the law, throughout England. The London College of Physicians have the power to prevent all but their own Fellows and Licentiates from practising as physicians in the Metropolis, but they have long ceased to exercise it.

PROVINCIAL
MEDICAL & SURGICAL JOURNAL.

CLINICAL LECTURE ON DIABETES,

Delivered at Kings College Hospital,

By R. B. Todd, M.D., F.R.S., Fellow of the Royal College of Physicians, &c.

(Reported by S. J. A. Salter, Esq., M.R.C.S.)

Gentlemen,—Most of you, I doubt not, are aware that at the present time there are no less than three cases of diabetes in the hospital, and considering that diabetes is not a very common disease, the occurrence of so many examples, all under our observation at once, offers us an unusually favourable opportunity of studying this malady, and I would here, in passing, express my belief that there is no way in which clinical study can be prosecuted with so much advantage as when we have several cases of the same kind before us at once, for we are then not only able to contrast the disease in its different stages, but also to observe what of the symptoms are common to all cases, and what are peculiar to individual instances alone.

The first of the cases, gentlemen, to which I shall direct your attention, is the man William Hardy, in Sutherland ward, who has been in the hospital since the 6th of July last. I will read you a brief outline of his case. He is 42 years of age; is a bricklayer by trade; he is a native of Essex, where he resided till within about twelve months before his admission into the hospital; his habits have been temperate, and it appears that his health has been for the most part good; he has, however, of late years, had occasional attacks of rheumatism, which was of a chronic muscular character. About two months previous to my seeing him, he had an attack of ague, from which he recovered, but this was shortly afterwards succeeded by catarrh, and since then he has never been in health. The first symptoms of the disease from which he is now suffering that he noticed, were great thirst and hunger, so that, to use his own expression, he "ate and drank all that came in his way;" added to this he remarked that he was rapidly losing flesh. He tells us that his thirst was most urgent, and that with what fluid he satisfied it, was quite a secondary object to him. This reminds me of a case which you may find in a recent volume of the *London Medical Gazette*, of a patient of Dr. Percy. This poor man suffered so intensely from thirst, that he would actually get up in the night and steal the medicine from the bottles of the other patients in the ward, and would drink whatever they contained, even though it were black draught.

About a fortnight after the thirst became urgent, Hardy noticed great increase in the quantity of urine, and also that he constantly had a disagreeable sweet taste in his mouth. When he entered the hospital he had other symptoms,—pain in the loins, slight dyspnœa, which was increased on the slightest exertion. During the first twenty-four hours he was here he passed twelve pints of straw-coloured urine, of the specific gravity of 1035. I also noticed a peculiar whitish chylous-looking exudation from the gums, which was more conspicuous upon pressing them with the point of the finger. The constipation was at first extremely obstinate, so much so indeed, that I thought at one time he was going to die from some internal obstruction, which we should be unable to overcome; this, however, has since very much given way.

Before I proceed any farther, I will advert to the point, which above all others, is the most interesting and important in the whole pathology of diabetes, and that is, the saccharine condition of the urine. I here show you a specimen of it, which was passed by the patient whose case we are considering; it is of a light lemon colour, with a peculiar cheesy odour. The best method for proving the presence of sugar consists in adding to a portion of the urine, in a test tube, an equal amount of Liquor Potassæ, and boil the mixture. I here exhibit to you this test, and observe, that as the fluid begins to boil, its colour, which was at first rendered lighter by the admixture of the colourless alkali, gradually passes to a fine deep reddish brown, a change which chemists tell us is produced by the sugar being converted into brown melassic acid; and if there is any superabundance of phosphates, as there usually is in these specimens of urine, they will be thrown down in the form of a white cloud, when the Liquor Potassæ is added. This test was first proposed by Mr. Moore, of Birmingham; it has the advantage of being very simple, and almost entirely free from fallacy. Not long since, however, Dr. Rees stated in the *Medical Gazette*, that in certain specimens of albuminous urine, quite free from sugar, he had known Liquor Potassæ and heat produce the brown red colour which indicates sugar. After this I examined albuminous urine with Liquor Potassæ and heat frequently, but in every instance the urine was made paler than before. Dr. Rees now states, that it is only impure Liquor Potassæ which produces the brown colour, when acting upon albuminous urine; so that you may

avoid all fallacy by using pure alkali, and keeping it pure, which may readily be done by preserving it in a dark green glass bottle, with a secure stopper. If, however, you should require further tests, there are several at your command. One of these is founded upon the action which yeast has upon sugar, converting it into alcohol and carbonic acid; so that by a proper arrangement you may witness the disengagement of the bubbles of carbonic acid gas. Then, again, you may obtain the sugar itself by simply evaporating the urine, and have it in a state of tolerable purity by treating the residue with boiling alcohol, from which menstruum the sugar will deposit in a crystalline form as it cools. Another test consists in leaving a portion of the urine exposed in a warm place for a day or two, and then examining it under the microscope, when you will find that the Torula or yeast plant has been developed.

There is yet another—Trommer's test, which depends upon the power which diabetic sugar has of deoxidizing oxide of copper, and converting it into the yellow binoxide. But all these tests, with the exception of Moore's and Trommer's, take time and trouble, and for all practical purposes, the effect produced by Liquor Potassæ and heat are perfectly satisfactory.

But, to return to our patient; there is another symptom which we must not overlook, and one which is constantly met with in diabetic subjects; it is *acidity of saliva*. You will find upon introducing a slip of litmus paper into his mouth, that it is reddened very decidedly. Another very remarkable fact which is frequently observed in cases of diabetes is, that the quantity of urine which is voided exceeds the amount of fluid drunk. In this case we have a good opportunity of observing this circumstance, for through the diligence of my clinical clerk, I have been furnished with an accurate and almost daily account, drawn up in a tabular form. The following are the results of some of his measurements:—

Date.	Quantity drunk.	Quantity voided.
July 9	80 ounces.	134 ounces.
" 10	80 "	184 "
" 11	80 "	128 "

Then passing over some days, we find that on July 21st, the quantity drunk was five pints, and that voided seven pints. On the 26th a more remarkable difference was observed, the amount of fluid taken on that day being 150 ounces, and the urine amounted to 268 ounces.

Tenderness of the loins was another symptom exhibited by this man, when a smart blow was struck with the point of the fingers in that region. When first he came into the hospital he was in a state of extreme prostration, so that for some time I feared his disease would have been speedily fatal; he rallied however, from this state, and is now much stronger.

Our next diabetic patient, gentlemen, is Isaac Bowles, also in the Sutherland ward; he is 20 years of age, 22 years younger than the patient to whom I have just now been referring. He is a native of Kent, and a carter by occupation. There does not appear to be any hereditary tendency to disease in his family; his general health was always good up to the commencement of this present illness, which he dates back nine weeks from the time of his admission into the hospital, (October 9th, 1847.) The earliest symptoms that he noticed were extreme thirst, and frequent desire to pass his water, which was unnaturally abundant; and this required him to get out of bed two or three times every night; his appetite was craving.

When I first saw him these were his symptoms:—Urgent thirst and hunger; frequent micturition, which, as was the case with Hardy, is worse at night; a sense of sinking and weight at the epigastrium; unpleasant but not sweet taste in the mouth; bowels greatly confined and evacuations scybalous; pain in the loins; mouth clammy; and I observed here, too, the white chylous exudation from the gums. The quantity of urine voided in twenty-four hours averages from five to six pints; the physical characters of this urine are very much as in that of our other patient, but it is somewhat denser, its specific gravity ranging from 1035 to 1040, this difference, doubtless, arising from the circumstance that less urine is voided. No accurate comparative table of the quantity of liquid taken and evacuated by this patient has been made; but I find in the report of the 12th of October, in the case-book, that the fluids drunk by the patient on that day measured in all five pints, and the urine voided by him five pints eight ounces, showing, that in this respect, this patient exhibits the same symptom as Hardy.

Stephen Dungay, who is the subject of the third case, is 22 years of age, and was admitted into Fisk ward, on the 10th of October; is an apprentice to a currier. Is not aware of any hereditary predisposition to phthisis or gout; his general health was good till he was eighteen years of age. At this time he had what he was told was a "slow fever," which prevented him from working, but did not confine him to bed. He states that the principal symptoms were headache, weakness and lassitude, with loss of appetite. He had no cough; there was great diaphoresis, but it was not preceded by rigors. He continued in this state for ten weeks, after which time he found he had acquired a craving appetite, and insatiable thirst, and that the quantity of urine he voided was much increased. These symptoms have now lasted four years, and have continued unabated up to the present time; and from the period when they first became marked, until now, he has been in the habit of getting out of bed two or three times every night to make water. The quantity of urine that he passes ranges from five to ten pints daily, and its average specific gravity is 1042.

The following is a tabular view of the quantity of fluids drunk and voided by this patient:—

Date.	Quantity drunk.	Quantity voided.
Oct. 15	120 ounces	124 ounces.
" 16	120 "	136 "
" 18	140 "	160 "
" 19	170 "	208 "
" 20	120 "	136 "
" 21	120 "	120 "
" 22	120 "	140 "
" 23	140 "	124 "

This man has had other symptoms, as pain in the loins, and the white exudation from the gums, like the other patients, but unlike them he has had diarrhœa. With this last exception, all these cases have had a remarkable analogy, as to their mode of access, progress, and duration, and I fear that they must all necessarily, sooner or later, come to the same termination.

I will, now, gentlemen, re-consider these four points, and make some general observations on them, in the order in which they are enumerated.

And first, then, as to the *access* of diabetes. We see that in all our cases the primary symptoms were referable to the stomach; they indicated stomach disorder,—the hunger, the thirst, the clammy state of the tongue and mouth generally, the sweet taste, the exudation about the gums all pointed to the same organ; and what is so remarkable is, that, unlike other stomach disorders generally, the digesting power of that viscus, as regards certain kinds of food, is enormously great, far exceeding anything that we ever witness in health. Our three patients take large quantities of food, but they do not suffer in any great degree from flatulence, epigastric tenderness, or weight. I think, gentlemen, any of you whom I see around me, and who have all the appearance of health, would feel extremely uncomfortable if you were to take in the course of the day or at a single meal, even half of what any of our diabetic patients take, and which is scarcely sufficient to satisfy them.

The *progress* of the complaint is not rapid; one patient, Dungay, has had it for four years in a very confirmed form, and many people have it for a longer period. The establishment of the disease, however, is rapid; that is to say, a person may be quite healthy, without a vestige of sugar in his urine, and in a very short time he will be suffering from the most marked symptoms of the disease.

As to its *duration*, it is evidently in the majority of cases, a chronic and not an acute malady. I take it that acute diabetes occurring to a person in previous good health and running rapidly to a fatal termination, is a thing of extremely rare occurrence. One of our patients has been suffering for four years, and has during the whole of that time, been indulging his appetite to the full; and this gives us an opportunity of observing the natural history of the disease, unmodified by medical interference, and shows us that under those circumstances the disease is a chronic one. The other patients have been ill less time,—Hardy about four months, and Bowles from two to three months. These, however, give us no measure of its duration. I have now in my private practice three cases of diabetes, all of which are of long standing. One of these I have had under my care for three or four years, and he had been ill nearly as long before he came to me. Another only a few months, but he had previously been under the care of another physician for more than twelve months. There is an important point in the natural history of diabetes, which has not been illustrated by either of my hospital patients; it is this, sometimes all at once, and completely, the diabetic symptoms cease, and are absent altogether for an indefinite period, at the expiration of which they return and destroy the patient; or they may allow him several intervals of rest, but they are sure to return ultimately, and make the patient their victim. I have lately been consulted by a patient on account of pulmonary disease, who some years ago was under the care of Dr. Prout, who pronounced him to be suffering from diabetes; and Dr. Prout is the highest authority upon this subject in this country. But now, though the urine has been examined with great care, not a trace of sugar can be found. I know of another case, that of a lady, who had confirmed diabetes; her physician, Dr. Babington, who mentioned the case to me, sent her to Clifton, to drink the Clifton waters, and in a short time she was well. She had a complete intermission of her disease, and this lasted for a considerable period, when it returned. She again went to Clifton and got well, but upon leaving, the disease returned. I do not know what became of her afterwards. You will at once perceive that the interest of this feature in the natural history of diabetes consists in the bearing it has upon inferences respecting the influence of remedies. It is true that, in the latter case, the Clifton air and waters may have had much to do with the suspension of the disease; and were this the only instance of such suspension of the diabetic state, perhaps the inference would be unavoidable, but sach is not the fact.

As regards the *termination* of diabetes, I fear we shall too soon witness that which is its constant termination, in the case of Dungay, in the Fisk ward; he is now much depressed, and is greatly emaciated, and does not rally under the stimulating and nutritive treatment and diet we have given him. I strongly suspect he has tubercles in the lungs, though as yet I have not satisfied myself of the fact, but I see in the case book that my clinical clerk has reported a dulness on the lower part of the right side; this, however, may arise from some enlargement of the liver.

Tuberculous disease of the lungs, gentlemen, is certainly the most frequent consequence of diabetes, and very commonly not only interferes with the influence of the treatment, but puts a termination to the disease by killing the patient. The cachectic state induced by the discharge of the large amount of solids by the urine, and by the imperfection of the assimilating powers, leads to the development of phthisis. I think it is a point for investigation whether the reverse of this does not sometimes happen, and not unfrequently,—whether, in fact, patients who are suffering from phthisis, do not become diabetic without their having been so previously. Of this I am convinced, that if you were to examine carefully the urine of all the phthisical patients who come into the hospital, you would find traces of sugar more frequently than is generally supposed. I recollect one case in point which occurred at a time when I was endeavouring to ascertain the just value of Moore's test, and it made the more impression on my mind, as I was led at first to question the evidence which that test gives of the presence of sugar, and which previously I had so much trusted in.

I had already tested the urine of several patients, when I came to a specimen passed by a patient labouring under phthisis, and then I found that the addition of Liquor Potassæ and heat caused the brown colour characteristic of the presence of sugar; I had then some misgivings as to the truth of Moore's test, but I afterwards proved by other tests that this urine did really contain sugar.

The great exhaustion which is so constantly present near the termination of diabetic cases, is doubtless owing to the large amount of waste that occurs in the system, from the constant excretion of such enormous quantities of solid matter by the urine. One frequent termination of diabetes is the supervention of some fatal acute disease,—inflammation, for instance, of one of the serous membranes; pleurisy, or peritonitis, but especially pleurisy,—and this occurs generally in cold weather, or after some unusual exposure; and from this we learn an important hint as regards our treatment, that our patients should be carefully clothed, and kept in a temperature as equable as possible.

It is remarkable that this same tendency to acute inflammations exists in those diseases of the kidney, such as Bright's disease, chronic nephritis, which so far resemble diabetes, that a material foreign to the blood is suffered to accumulate in that fluid, and solid material which is foreign to the healthy secretion, excites irritation in certain organs and tissues.

We are now come to the most interesting and the most difficult point in our inquiry respecting diabetes, and that is, as to what the disease essentially is, and in what its true nature consists. We know the fact that there is an enormous development of sugar, and also in some cases an increase in the amount of urea, though this was at one time denied; for it was then thought that the urea was diminished, or even lost altogether, and replaced by the sugar; in short, that those two substances were vicarious of each other. This, however, is not the case; but it is remarkable, that though the occurrence of sugar does not cause a decrease in the amount of urea in the urine, still sometimes the sugar will disappear for a few days, the urine nevertheless retaining its high specific gravity, on account of the presence of a large quantity of urea. Sometimes lithic acid is present in the urine in excess.

As regards the development of sugar in diabetes, there are three important questions which suggest themselves to us,—namely, where is the sugar generated?—what is its source?—and, what causes the generation of this sugar?

These questions have as yet never been answered in a satisfactory manner; had they indeed been answered, the essential nature of the disease would no longer be enigmatical.

Let us now briefly consider what we know of these several points, and, first, as to the locality where sugar is generated. There is no doubt that this change takes place somewhere in the upper part of the alimentary canal—most probably in the stomach; for if you give a diabetic patient an emetic two or three hours after he has taken a meal, you may find sugar in large quantity in the matters vomited. This experiment has often been made, and always with the same results, so that there can be little doubt that the development of sugar occurs first in the stomach itself.

The question raised as to what is the source of this sugar, is not so easily answered. The first point to settle is, whether it is produced by the mucous membrane, by any process allied to secretion, or whether the food, on being taken into the stomach, is immediately changed into sugar; and assuming the latter to be correct, a further question would arise as to whether the whole of the food, or only a certain portion of it, underwent this transformation. Though we have no very positive evidence of the fact, still there is reason, judging from analogy, to believe, that the latter is to a great extent the true explanation,—that the sugar is generated in the stomach from the food, and that certain portions only of the food undergo this change.

There are several substances in the vegetable kingdom which we employ as food, which in there ultimate composition are closely allied to sugar, such as gum, starch, &c.; and these, by chemical processes, can, out of the body, be converted into sugar. To take an example; if you mix starch and some saliva, and then keep them for some time at a temperature of 100° Fahrenheit, the nature of the starch is destroyed,—it becomes sugar, has a sweet taste, and will ferment; in fact it has all the saccharine properties; and what is still more remarkable is, that the sugar thus produced has some peculiarities which are met with only in grape and diabetic sugar, which are identical in nature and properties. This fact at once suggests the idea that the starchy materials of the food are the source of the sugar, and that they consequently ought to be removed from the patient's diet. This practice has been long pursued, and with a certain amount of success.

But, may not the nitrogenous aliments be converted into sugar? This point has frequently been endeavoured to be settled; but it is very difficult to come to any definite conclusion, for, however you may deny your patients the use of saccharine and vegetable food, such is their craving for this kind of aliment that they are sure by some means to obtain it in spite of the utmost precautions. I propose, however, to try an experiment on this point with one or two of our patients. I shall propose to them to be separated from all the other patients, and be shut up as prisoners in a small ward, keep them locked in, and allow them no communication except with the nurse, or other trust-worthy persons. When each patient is first introduced to his prison I shall order him an emetic and a purgative, and after that I shall give him, as his diet, beef, mutton, and eggs, and allow him simple water to drink; and in three or four days, make a careful examination of the contents of his stomach after the operation of an emetic, and shall have his urine examined as to the amount of sugar it contains. In a future lecture I shall communicate to you the results of this experiment.

Besides being found in the urine and fæces, and imparting a sweet taste to the saliva in the mouth, the sugar may be detected in the blood; this has but seldom been accomplished on account of the minuteness of the quantity which it contains, for the sugar has such

a diuretic action on the kidneys, that it passes off in the urine almost immediately after it has entered the circulation.

I told you just now, that when you submit a portion of starch to the action of saliva and heat, it is converted into sugar, there being some substance in saliva which has the power of producing this change. This is exactly what takes place in the natural transformation which occurs to the starch of seeds, converting that into sugar, and in this instance, the body which produces it has been isolated, and to it the name "*diastase*" has been applied.

A question here suggests itself, is there in this disease, any animal diastase generated either in the saliva, gastric juice, or pancreatic secretion? Or, according to the view lately proposed by Mialhe, is the substance (the diastase,) already existing in healthy saliva, and which we have seen can convert starch into sugar, increased to an abnormal degree? Whichever of these is the explanation, there can certainly be no doubt but that the saliva is in an unhealthy condition, for in each of the three cases which we have investigated to day you will remember the saliva was strongly acid, and this is the case almost uniformly in diabetes. Now, this constantly acid state of the saliva, is an unnatural condition of that fluid, for it generally causes an alkaline reaction or is neutral during health.

The locality at which the change of starch into sugar is effected, is undoubtedly, in great part at least, the stomach, but I do not believe that the secretion of that organ has any effect in producing the change. Tiedemann and Gmelin, also Dr. Prout, have thought that the gastric juice has this property, but it has since been proved by experiment that no such effect can be caused, for by digesting starch with gastric juice, at a temperature of 100° Fahrenheit, no sugar is generated. Gastric fluid has the power of digesting the albuminous portion of food, but its effect on the amylaceous is simply maceration. Indeed it seems most probable that amylaceous matters are only digested by the saliva and the secretion of the pancreas, which is, in fact, only a large salivary gland.

It has been shown by Bouchardat and Sandras, and I have repeated their experiments, that the fluid secreted by the pancreas has the property, like saliva, of converting starch into sugar; and Bouchardat holds that in diabetes not only have the pancreatic fluid and saliva this animal diastase, as in health, but that the gastric juice likewise contains it, and that the sugar is produced directly from the food by its action upon the amylaceous portion; and he believes that if the patients be prevented from taking amylaceous food, the formation of sugar will be suspended. Upon this view of the subject Bouchardat founds his mode of treatment by regulating the patient's diet, and denying them all vegetable food; and so successful has this plan been in his hands, that he tells us that of forty-one cases, the following were the results:—

16 cured.
14 relieved.
11 died from phthisis.

This, however, is, I apprehend, far greater encouragement than we meet with in this country, even from a similar mode of treatment.

In another lecture I shall examine these points a little further, and discuss the various modes of treatment of this disease.

PUERPERAL FEVER;

IN WHAT WAY IT MAY ORIGINATE FROM ERYSIPELAS, AND HOW COMMUNICABLE.

By R. U. West, Surgeon, Hogsthorpe, Lincolnshire.

The following cases, which are corroborative of the opinion that puerperal fever may originate from attendance on erysipelatous patients, and that a malady so originating is communicable from one puerperal woman to another, are also suggestive of other conclusions on this painful subject, which are, I think, of some practical importance.

On the 6th of January, 1842, I was called in to attend an elderly gentleman in this village, who had erysipelas of the face. As yet his symptoms were not at all urgent; it appeared to be quite a slight and common case. I sent some saline medicine, and a lotion. The same evening I attended a case of midwifery, two miles from my residence. The next morning, before visiting my erysipelatous patient, I attended a second case of midwifery, four miles from my residence. On my return home, I found my patient considerably worse; I applied nitrate of silver freely all over the affected part. At one or two o'clock in the morning of the next day, January 8th, I was called up to him. He was much worse; face and head frightfully swollen down to the shoulders on both sides. After visiting him again the some morning at nine o'clock, I called upon both my lying-in patients. They were doing well, and in fact recovered without a single bad symptom. In the evening I found the old gentleman in a very bad way; there was some delirium, and the head and face were still more swollen. I made a few punctures in both cheeks, and while busy with him was sent for in all haste to attend a case of midwifery,—Mrs. T. T., of L——, a distance of three miles. I believe I went without washing my hands. I was not detained more than a couple of hours, and as I was riding homewards, I was met by my groom, who had been sent to me with the announcement that an alarming change had taken place with my erysipelatous patient. I hastened on, and found him comatose, with a dusky livid appearance of the face. He died in the course of the night, a frightful spectacle.

And now commenced my troubles. In the night of the 9th of January, or rather early in the morning of the 10th, I was again summoned to Mrs. T. T. I found her in the following state:—Very severe pain, aggravated in paroxysms, like after-pains; some abdominal tenderness; had had a shivering fit; some headache; no anxiety of countenance; pulse 120, soft and full; skin hot; diaphoresis; lochia abundant; no signs of milk, but as it was barely thirty hours after delivery, it was quite early enough for that. I ordered

fomentations, and sent some doses of Dover's powder in a saline mixture. Eight hours after, pulse 100; felt much better. Sent her an opening powder,—calomel and rhubarb.

January 11th. Pulse 112; more pain again, with tenderness; *complained much of pain and heat of the vulva.* Ordered eight leeches to the abdomen, and four to the vulva, and gave her a grain of calomel and three grains of Dover's powder with saline mixture every four hours.

12th. Tenderness increased; abdomen tympanitic; pulse 130, smaller, but not sharp; some anxiety; lochia still abundant; no milk; tongue white and slimy. I proposed venesection, but finding the husband inclined to be dissatisfied, I made him fetch my friend Dr. Barker, of Spilsby, with whose sanction I bled the patient. The medicines were continued.

13th. Pulse below 100; pain better; abdomen very full; did not pass sufficient water.

She continued to improve till January 16th, though very nervous and timid, and on that account giving a good deal of trouble, but in the evening of that day I found it necessary to pass the catheter, which had to be repeated once or twice a day until the 26th, when the retention, after resisting various medicines, such as Tinctura Lyttæ, strychnine, mucilage with Liquor Potassæ, &c., yielded at once to the Tinctura Ferri Muriatis, in doses of fifteen drops every four hours. The pulse never got above 100 after the venesection. She continued weakly for about a month.

On the 15th of January, at one o'clock in the morning, I attended a case of midwifery in a village about six miles from my residence. The woman had "got it over" before my arrival; I had not even occasion to remove the placenta. I, however, felt her pulse, of course, besides ascertaining by pressing the abdomen, that the uterus was safely contracted, which I never omit to do before leaving a lying-in woman.

On the 17th I called upon this patient again, after having in the morning passed the catheter for Mrs. T. T. She was getting on well, and *recovered without the occurrence of a single unpleasant symptom.*

In the evening of the 16th of January, immediately after my return home from a visit to Mrs. T. T., on which occasion, be it remembered, I had been obliged to use the catheter, I was summoned to attend Mrs. R. B., of C., about a mile from my residence. I was with her about an hour before she was delivered; it was her fourth child, and her labour was easier and quicker than common.

On the 18th, in the morning, being about thirty-six hours after her delivery, I was again summoned to this patient. She was suffering very severely from constant pain in the abdomen, aggravated in paroxysms, (which I have generally found to be the case in *puerperal* peritonitis;) there was very considerable tenderness on pressure; pain in the forehead; pulse 130, small and sharp; respiration hurried; countenance flushed and anxious; restlessness; lochial discharge slight; bowels confined; some nausea; tongue white; skin hot; could not find that she had had any rigors. I bled her in the arm immediately, after which the pulse dropped to 100, and the pain was somewhat abated. Sent an opening powder, and some fever medicine.

When I called in the evening the aperient had not acted; the pain had returned as bad as ever, the tenderness being excessive; pulse 130, as at first. I took some more blood from the arm, and gave her an enema, which brought away some scybala. The pains were now materially relieved, though the pulse did not drop this time. Sent an opening mixture, with Magn. Sulph. and Tinct. Hyoscyami.

19th. Felt better; purged two or three times; no return of paroxysmal pains; tenderness still remaining; pulse 130. The milk had appeared in the breasts, which I looked upon as favourable.

20th. Complete retention of urine, causing pain and tenderness again. Passed the catheter, which gave great relief. In other respects better.

21st. No water passed since the catheter was used at noon the day before, catheterism therefore necessary both morning and evening; there was still *malaise* though the symptoms were apparently less urgent; there was still pain, with abdominal tenderness; and the pulse was never below 130. I therefore this day gave calomel and opium in pills, and applied a dozen leeches to the abdomen.

The next morning, January 22nd, the catheter was not needed; there was some tendency to diarrhœa, and she had a severe rigor. I found all the symptoms aggravated. Any further depletion I could not venture upon; on the contrary, I sent some aromatic confection, continuing the calomel.

I saw her twice or three times on this day. I was called up the next night, and finding the result likely to be fatal, persuaded the husband to fetch Dr. Barker. By the time he arrived, in the course of the morning of the 23rd, the poor woman was beginning to be typhoid; she had been at times delirious; there was tympanitic distension of the abdomen, with other untoward symptoms. We gave carbonate of ammonia, to which was added wine the next day.

On the 25th she was quite typhoid; black tongue; subsultus tendinum distressingly frequent; hiccup, &c.; and in the evening of the same day she sank. A constipated state of the bowels in the first instance seemed to complicate the disease unfavourably. There were some scybala voided even on the 23rd. The milk continued in the breasts to the last; its appearance, therefore, in this disease, is not critical.

Dr. Barker and I discussed the matter most anxiously while he was with me on the 23rd, and although we were both of us quite unconscious that the case of erysipelas had had anything to do with the puerperal affection, we felt compelled to the decision that Mrs. R. B.'s case was genuine malignant puerperal fever, and that as it had probably been communicated from Mrs. T. T., my only safe course to prevent its further spread would be to discontinue attending midwifery for a time. I therefore at once sent for a substitute. But before his arrival (I had 23 miles to send,) I was *obliged* to attend another midwifery case. Oh! how anxious I was. I changed all my clothes before going; washed

my hands in several waters, with solution of chloride of lime, and although I delivered the woman, I was careful to make as few examinations as possible. This case, it will be understood was attended on the 23rd of January. The woman had some slight symptoms of peritonitis on the 25th; her pulse was very frequent, and there was severe pain with some tenderness. She had some saline aperient medicine, with fomentations, and did well.

As soon as I could be released from my attendance on Mrs. T. T.,—for I did not think it prudent to allow my substitute to pass the catheter for her,—I went into Leicestershire for a fortnight. I am happy to say that I have not seen a case of malignant puerperal fever since, though I have, as may be supposed, seen several cases of simple peritonitis.

I may be allowed to observe upon the above accurate detail of facts, that if it be conceded that my attendance on the case of erysipelas was the cause of this formidable malady getting into my practice, which, painful as the thought may be, I think was the case, it seems probable:—

First. That as the cases attended on the 6th and 7th of January, recovered without the appearance of any unfavourable symptoms, a form of erysipelas, which may supsequently in its *malignant* and almost *putrid* stage originate puerperal fever, will not do so in its *early* stage.

Secondly. That as the disease did not come on in the the same patients, notwithstanding my visiting them after attending the erysipelatous case when the symptoms *had* become formidable, the merely taking a lying-in woman by the hand will not originate the disease.

Thirdly. That as the woman attended on the 15th of January recovered without any symptoms of the malady, although I might at the time, be supposed to be tainted with both the erysipelas and the puerperal disease of Mrs. T. T., it requires something more than a mere *visit* to a parturient woman to communicate the disease from one puerperal patient to another.*

Fourthly. That, bearing in mind the above suppositions, the circumstances immediately preceding and accompanying the attendances on both Mrs. T. T. and Mrs. R. B., go to prove that it requires actual contact of the accoucheur's infected hand with the mucous membrane of the vagina, both to originate and communicate the disease. (Query—would not the heat and pain of the vulva in the first case confirm or strengthen this supposition?)

Fifthly. That the slight manner in which the disease appeared in the woman attended on the 23rd, (notwithstanding I was still passing the catheter daily for Mrs. T. T., and had but just returned from a visit to Mrs. R.B., the latter being at the time almost typhoid,) would serve to prove that ablution, change of clothes, chlorides, &c., are of some little avail.

Sixthly. That erysipelas may originate a *mild* form of puerperal fever, which may in its turn communicate a *more malignant* form. (In the two cases here alluded to, the symptoms in the commencement were nearly the same, the occurrence of dysuria in them both being somewhat remarkable; the fatal difference was in their *terminations*,—typhus and death in the one, gradual recovery in the other.)

And, *lastly*, that a puerperal fever, originating from a case of erysipelas, is not *necessarily fatal*.

I offer the above remarks with considerable diffidence. The *facts* I have detailed may be relied on, and I leave the reader to found upon them what conclusions he may please.

Hogsthorpe, Lincolnshire,
February 12, 1848.

* From what Dr. Blundell says in his lectures, (*vide Lancet*, for August, 30th, 1828, page 677,) he appears to think a mere visit dangerous.

CASE OF OVARIAN DISEASE.

By George Kennion, M.D., Harrogate.

I was consulted by Mrs. W., the housekeeper in a family in this neighbourhood, a single woman, aged 34, on account of a large abdominal tumour, which she had first perceived about two years previously, and which had gradually increased up to the present time, her size being that of a woman in the eighth month of pregnancy. There was little difficulty in ascertaining that this tumour was a large ovarian cyst, apparently unilocular. The catamenia had been absent for two years, but in every other respect her health was perfectly good. As her case seemed appropriate for the operation of tapping, I advised her to have this operation performed, but to postpone it as long as she could possibly do so.

On the 15th of September I was requested to see her again, and found that the cyst had greatly increased in size. The abdominal parietes were exceedingly tense and thin, and she could neither walk, sit, nor lie down without the greatest discomfort, I therefore decided that the operation should be no longer postponed, and it was accordingly performed upon the 18th, with much tact, by my friend Mr. Beaumont, the usual attendant of the family. The fluid was of an oily consistence; the colour was remarkable, being almost as red as blood. Mrs. W. bore the operation (which was rendered more complicated by the presence of a second and smaller sac, which we could not detect until after the removal of the fluid from the principal sac,) exceedingly well; and, although we were not satisfied with the character of the fluid which was withdrawn, there was no reason to apprehend any untoward result.

I was sent for to see her with Mr. Beaumont upon the evening of the 22nd, and found her with an exceedingly quick and weak thready pulse, an anxious haggard expression, constant jactitation, and complete anorexia. There had been *no rigor*. She had no pain

nor tenderness in the abdomen, and the cyst was rapidly re-filling.

These symptoms continued gradually to increase in spite of tonics, stimulants, opium, and as generous a diet as she could be induced to take, and were succeeded by hiccough, vomiting, aphthæ on the tongue; and she sank upon the 28th, being just ten days after the operation.

The *post-mortem* examination, which was conducted by Mr. Beaumont, was very interesting. The two sacs which had been so recently emptied had re-filled, even to a greater extent than before the operation, the character of the fluid being similar to that which had been previously withdrawn. There were a *very* few flakes of lymph in the larger sac, but with this exception their lining membranes presented no unusual appearance. Behind these sacs was a large irregular nodulated tumour, extending from one iliac fossa to the other, and reaching as high as the last dorsal vertebra. This tumour consisted of an enormous congeries of smaller ovarian cysts, varying from the size of a filbert to that of a plover's egg. All these cysts were matted together, so that both ovaries were amalgamated as it were into this large and shapeless mass, in the centre of which could be indistinctly traced the remains of the uterus, which by the constant pressure had been nearly absorbed. Each of these cysts contained a colourless fluid, of more or less consistence. The other organs of the body were quite healthy.

Although no practical benefit could arise from the narrative of this case, it is so interesting in a pathological point of view, that I have thought it right to place it upon record. Those who, like Mr. Safford Lee, are opposed to the operation of tapping in almost any case of ovarian dropsy, will probably consider that this case furnishes fresh support for their opinions; and indeed there can be but little doubt that the life of Mrs. W. might have been prolonged a few weeks, had the operation not been performed; but it would have been, at the best, a question of *weeks*, for the walls of the larger cyst were so exceedingly thin, that it must soon have ruptured, and our patient would in all probability have sunk under the tortures of acute peritonitis. On the other hand, with the healthy character of Mrs. W.'s constitution, and in the absence of other organic disease, there was every probability of her obtaining, with little risk, the relief which she sought. Indeed this case is one which, if it could be adduced as having *any* weight in a practical view, might serve as a beacon to those who are ever forward to advocate the removal of the ovarian sac; for no test could have discovered the existence of such extensive disease as the *post-mortem* examination of this case revealed to us; and had *extirpation* of the disease been attempted, how fearful the consequences must have been.

The treatment of ovarian dropsy is beset with so many difficulties, and, upon the whole, has been hitherto so unsucessful, that I fear we must consider this disease as one of the *opprobria medicinæ* with which our science is encumbered. I have never seen (and in this I am borne out by the highest authorities) any benefit arise from the use of medicine. Iodine I have tried, and have seen tried, with no good result whatever. Mercury is worse than useless. We can look for no assistance from purgatives or diuretics. What then remains to be done? In the *first* instance I would always recommend that the fluid be withdrawn, unless there existed any peculiarity in the case to forbid even this minor operation. When this has been done, I have the abdomen *tightly* bandaged, and this, we are told, will sometimes produce a radical cure. I have been so unfortunate as only to witness *one* case where this object has been accomplished. I have frequently seen it fail. The experience of others, however, upon whose reports the utmost reliance may be placed, is so far in favour of this plan, that I would *always* adopt it where it is practicable.

In one case which I attended in July, the bandage was tightly drawn over the abdomen in the course of two or three days after the fluid had been removed; but the effect of this was so much obstruction to the passage through the ascending vena cava, that œdema of the legs to the most frightful extent was induced before the termination of a week, and I was obliged to discontinue the bandage altogether. Of course, after the operation of tapping, care must be taken to keep up a regular but gentle action, both of the bowels and the kidneys; beyond this, the less we interfere with medicine the better.

If the sac rapidly *re-fills* after the first or second operation, I think we are justified in recommending the more formidable operation of extirpating the ovary, *provided that no other organic disease exists*; but if the return of the disease is slow, and occupies many months, or a year or more, the danger to the patient is, I think, so trifling, *as long as this state of things continues*, that it would be wrong, in my opinion, to perform so hazardous an operation.

BUCHU IN DROPSY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Observing in your Journal of November 3rd, a communication from "A Member," strongly advocating the efficacy of "Diosma crenata," in some dropsical affections, and having shortly after two cases, one of ascites dependent upon a disordered state of the liver, and the other scarlatinal dropsy, I was induced to make a trial of the buchu, and I am happy to say, with good effect. It is not the first time I have seen the beneficial use of buchu, but as I believe it is not now so much in fashion as formerly, I herewith send you a history of the cases, and as a member of the Association, (if you think them worthy a place in the Journal,) I shall feel obliged by their insertion.

I am, Sir, yours &c.,

EDWARD HOSKINS, M.R.C.S.E., &c.

Loughborough, Dec. 12, 1847.

CASE I.

November 8th, 1847. Mrs. M., aged 47, of dyspeptic habit, has been suffering for some days past from pain

and tenderness in the right hypochondrium, with pain in the right shoulder; appetite bad; foul tongue and great thirst; complains of a sense of distension after meals, with flatulence; bowels costive; urine scanty and high coloured, with œdema of the legs and ankles, and swelling and fluctuation of the abdomen.

R. Pil. Hydrarg., gr. v.; Extr. Coloc. Co., gr. vj. M. Fiat pil. ij., hora somni sumend. R. Haust. Salin. Aper., primo mane sumend.

9th. Bowels well acted upon, the evacuations being of a clay colour; other symptoms about the same.

R. Pil. Hydrarg., gr. iij.; Pulv. Scillæ, Digitalis, utrq., gr. j. M. Fiat pilula, mane et vespere sumenda.

R. Potass. Iodid., scr. ij.; Tinct. Hyoscyami, dr. ij.; Infusi Cascarillæ, oz. vj.; M. Capt. cochl. tria ter indies.

11th. Legs and ankles considerably œdematous; more swelling of abdomen; breathing difficult in the recumbent posture; great thirst; urine still scanty and high coloured.

To continue the pills. To omit the former mixture and to take the following:—R. Potassæ Bicarbon., dr. j.; Infusi Buchu, oz. vj. M. Capt. cochl. ampla iij., quarta quaque hora. To drink broom-tea, and to have an ointment of tartar emetic and iodide of potassium rubbed into the right side.

13th. Symptoms alleviated; has passed more urine; slept better; thirst diminished; bowels confined.

To continue the medicines; to have an aperient draught containing one scruple of Pulvis Jalapæ Comp.

17th. Greatly improved; has passed large quantities of urine; the skin from being dry and harsh, has become cool and moist; tongue clean; no œdema of the legs and ankles, and decidedly less swelling of the abdomen; is able to lie down comfortably; sleeps much better; appetite improved.

To omit the blue pill and squill, and to have—R. Pil. Plummerii, gr. iv.; Extr. Hyoscyami, gr. v. M. Fiant pil. ij., hora somni omni nocte sumend. To continue the mixture.

19th. From this time she began to amend rapidly. Has been latterly much purged, whether from the buchu or not I am unable to say; the evacuations the same as from the use of hydragogues; the kidneys have been powerfully acted upon, and she has continued to pass large quantities of urine. On the 24th there was no swelling of the abdomen whatever, and on the 26th, she was so far convalescent as to be enabled to go into the country.

Case II.

M. R., aged 14. This was a case of anasarca, succeeding about the usual period, a mild attack of scarlatina. It resisted the treatment which I adopted in the first instance, of bark and aromatic confection, and the symptoms became aggravated, and on November 18th, there was great thirst, quick pulse, white tongue, and constipated bowels, the dropsy in this case, as Dr. Gregory states, depending upon a continuance of a highly excited state of the cutaneous capillaries, which, earlier in the disease, occasions desquamation of the cuticle. After the exhibitions of saline purgatives, combined with small doses of digitalis, I again tried the buchu, with the same good effects as before, and in a few days the dropsy disappeared. In this case also, there was great purging, when the buchu had been taken for a short time, and also an abundant secretion of urine.

SHORT NOTES OF THE OPINIONS AND PRACTICE OF THE LATE JOHN PEARSON, ESQ., F.R.S., ON SYPHILITIC DISEASE.*

By W. S. Oke, M.D., Physician to the Royal South Hants Infirmary.

Ulcers on the Nipple, Navel, Alæ Nasi, aad Upper Lip.—Ulcerations of the areola and nipple in both sexes, particularly in women, are very tender to the touch, and discharge a thin ichorous fluid. When of long continuance they occasion inflammation and abscess of the breast. They occur chiefly in pregnant women who have lues, but they occur so rarely as not to be seen perhaps in more than one case out of 500. In the umbilicus also ulcers are more frequent in women than in men, and are very offensive.

When the alæ nasi and upper lip are affected by venereal ulcer, a pimple will form, and discharge an ichor; or there may be soreness and excoriation produced, which if suffered to go on will destroy the alæ. The sore always spreads from the angle between the cheek and nose, and frequently degenerates into a painful spreading ulcer, which will sometimes extend to, and destroy, the upper lip. These cases are not common. Cancer generally affects the lower lip; but the secondary sore from syphilitic poison usually attacks the upper lip.

Local Treatment of Ulcers of the Nipple, Umbilicus, Alæ Nasi, and Upper Lip.—In the treatment of the two first, cleanliness must be insisted on. Where the nipple is sore and inflamed, a poultice, made with linseed meal and Goulard water, may be applied till the swelling is reduced; afterwards a solution of the Argenti Nitras, or of the bi-chloride of mercury, may be used. The wash, commonly called "the black wash," may be tried; but no greasy application should be made use of. Sometimes these sores will not heal till after delivery.

The same mode of treatment will be applicable to ulcers on the umbilicus. Ulcers on the alæ nasi and upper lip may be dressed with the Unguentum Hydrargyri Nitrico-Oxidi, and occasionally touched with a solution of the nitrate of silver.

[*Case.*—A female, of middle age, consulted me for an ulcer on the left ala nasi. It occupied the greater part of the ala, which was much thickened. It was foul, with high jagged edges, and had all the appearance of a carcinomatous character. It produced great deformity of the countenance, had continued nearly twelve

* Continued from page 92.

months, and had resisted every means that had been tried to heal it. I at first doubted whether I should do her any good, but having been consulted by her some years previously for ulceration of the throat, I thought it probable that it might have a syphilitic origin. Accordingly, I prescribed five grains of the Pilula Hydrargyri every night, and four grains of the iodide of potassium three times a day, desiring that the ulcer might be washed twice a day with a little diluted tincture of myrrh. Under this treatment the sore completely healed in a month, and all hardness of the ala disappeared.]

Venereal Sarcocele.—This is a tumefaction of the testicle, and by no means a common occurrence. When it does occur, it is always connected with an affection of the skin. Both testicles are usually enlarged, and become soft and pulpy. There is also a fulness of the integuments, which are sometimes covered with tubercles or a scaly furfuraceous appearance. The swelling is pretty uniform, and there is not much pain nor any affection of the spermatic vessels. Suppuration of the scrotum rarely occurs from the syphilitic poison.

Syphilitic Affection of the Ears.—The sebaceous glands behind the ears, and upon the concha, and sometimes the whole cartilaginous substance, forming the external ear, are involved in the syphilitic action. The parts become thickened and painful, often discharging offensive matter; at other times the disease will extend to the Eustachian tubes, particularly where the tonsils and fauces are affected, producing tinnitus aurium. The ossicula auditûs are not so apt to be involved as in scrofula, and therefore deafness is probably the result of thickening of the parts. From this patients generally recover.

Intertrigo Syphilitica.—By intertrigo is meant n painful excoriation of the integuments, with an offensive ichorous discharge, often extending from the anterior to the posterior perineum; and on the inside of the upper part of the thigh there is sometimes a morbid surface, having a whitish appearance, and covered with a thick sebaceous matter. The patient is disturbed by it at night, and cannot sleep. The ulceration never becomes deep, and is seldom met with in the higher ranks of life. It is more the result of a want of cleanliness than a characteristic of lues, although it occurs in those affected with this disease. Intertrigo pudendi is often the result of gonorrhœa in women; it may also be produced by the action of mercury, when it looks as if the epithelium had been separated from the organs of generation.

Treatment of Venereal Sarcocele in Syphilitic Affection of the Ears and Intertrigo.—The swelling of the testicle will generally begin to subside when the mercury acts on the constitution; but if the disease proves obstinate, a warm solution of the muriate of ammonia, with vinegar, may be locally applied, or the camphorated spirits of wine, with a little of the Liquor Ammoniæ, made warm over a candle. Should the swelling of the testicle remain in an indolnet state, a poultice of the fresh leaves of hemlock may prove useful.

Ulcerations of the ears should be well washed with a decoction of poppies and chamomile flowers, and dressed with the Unguentum Hydrargyri Nitrico-Oxidi. If the ulceration extend to the internal ear, fumigation of cinnabar will be useful.

Intertrigo seldom demands much attention from the surgeon, and may be removed by interposing a silk handkerchief between the scrotum and thigh, supposing mercury to be always used. Intertrigo pudendi may be treated with Goulard water and lime water, to which a little spirit is added, or with a weak solution of the bichloride of mercury. A strong infusion of tea or camomile flowers will sometimes relieve the symptoms. Should there be much excoriation, the saturnine ointment or calamine cerate may be applied.

Intertrigo ani is by far the most painful, and is frequently so severe as not to admit of relief. Large doses of opium will be necessary to lessen irritation; and in these cases the form of powders answers better than unguents. Equal parts of powdered myrrh, white lead, and Lapis Calaminaris, may be tried, or the sulphate of zinc in powder; and the parts should be frequently washed with a soft sponge wrung out in warm elder flower water, or warm water only.

Warts and Excrescences.—Warts and excrescences may be considered diseases of the skin, and caused by spurious growth. When they remain after the total disappearance of the venereal symptoms, it is probable that in the majority of cases they will not again infect the constitution; there are, however, exceptions to the rule. There are cases where, after the removal of warts from the prepuce, &c, by excision, the sore will not heal, except under a course of mercury. Syphilitic warts may be divided into the verruca vulgaris, and acrochordis, and syphilitic excrescences into condylomata, fici, and cristæ. The common wart is a small, hard, and almost insensible tubercle, arising from the surface of the skin, covered with a dense cuticle, and of the colour of the integuments. They occur on the penis, nymphæ, perineum, &c., and especially in those who have had the venereal disease. They do not arise from the cuticle, and are always sensible. They are more luxuriant where the epidermis is kept moist by secretion, and are black in the negro. They are not to be considered as newly formed parts, but rather a redundancy of the normal parts, and hence their base does not increase, although the wart itself may acquire a considerable size.

The acrochord or pencil-shape kind springs from a moister surface,—viz., from within the labia of females, and is of a softer texture than the common wart; they are sometimes met with within the nose, where they are not always of the syphilitic character.

Condylomata are smooth, soft, and of a dark red colour; they are covered with cuticle, and not much elevated above the skin; their surface is as broad as their base, and they are commonly found about the anus. Sometimes they assume a shape and colour resembling figs, and hence are called fici.

Cristæ occur about the anus, perineum, and glans; they have a broad base, and a fimbriated appearance. When seedy they have been compared to a cauliflower. Sometimes they are produced in great number on the perineum of females, forming a large bulk, and discharging a most offensive ichorous matter. They sometimes occur in children, and without any venereal cause; they are not probably derived from the same sources as the common wart, but from the sebaceous glands of the part.

Treatment of Verrucæ, Condylomata, &c.—The hard warts may be destroyed by inflammation, decomposed by caustic, or extirpated by the knife. It is difficult to excite a sufficient inflammation to destroy warts, without injuring the surrounding parts. It is best first to soften them by a poultice, containing soda, after which the top is to be pared off, and a mineral acid applied, till the whole is destroyed. Where a ligature can be used it is a still better remedy, as the wart is then less liable to return. It is always applicable to the pencil kind. It appears that the part of the wart below the ligature dies as well as that above it. If the prepuce be studded with warts, it is better to remove it; and if there be masses of them on the penis, a small portion only should be destroyed at a time, lest the inflammation produce gangrene. Condylomata frequently shrink and disappear during the mercurial course, without any local application; if they should remain, a solution of the bi-chloride of mercury, or of mercury in dilute nitric acid may be used.

Cristæ are to be reckoned amongst the most inveterate venereal excrescences. They will be regenerated again and again. The most useful applications are the following:—A solution of the bi-chloride of mercury, the hydrochlorate of ammonia, powder of savin, acetate of copper, sesqui-chloridi of antimony, (butter of antimony,) arsenic and fumigations, with the bi-sulphuret of mercury. Those caustics which produce most inflammation, are the best. Should a crista, after having been destroyed by caustic, sprout up again, great benefit will be derived by a strong solution of alum in a decoction of oak bark. The following is recommended by Plenck:—

R. Alcohol, Aceti Destillati, utrq. ..... oz. iss.
Hydrargyri Bi-Chloridi ..... dr. j.
Aluminis Sulphatis, Camphoræ, utrq. dr. ss.
Misce. Fiat Lotio.

Whenever a ligature can be used in cases of cristæ it ought to be applied. A needle with a double ligature will be found the most effectual method of applying it. If it be thought fit to excise these excrescences, the excisions must be deep in order that the sebaceous glands, from which they probably spring, may be extirpated with them.

Rhagades.—Rhagades are fissures on the hands, about the anus, or perineum, and sometimes on the lips. It is important to distinguish the syphilitic from the common kind. The common rhagades are dry and give no disturbance but by their dryness; they sometimes appear like little nodes or corns in patients who have a tendency to lepra. Those which are derived from syphilitic causes may be distinguished by their being very painful and discharging profusely a fœtid matter.

Treatment of Rhagades.—Those on the hands generally begin to heal when the system is under the influence of mercury, and will get well without any local application, if attention be paid to cleanliness; those on the anus are very painful and difficult to heal. They should be dressed so as to expose the bottom of the sore, and the best application will be the Unguentum Hydrargyri Nitratis, or a solution of the nitrate of silver.

(To be continued.)

ON THE TAXIS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Some late numbers of your Journal contain communications on the subject of incarcerated hernia, which are calculated to cast imputations on the practice of some of the most eminent surgeons and most popular writers on surgery, from Desault to Druitt.

One of your correspondents, Mr. Hunt, seems fearless in maintaining his position in regard to the general practicability of the reduction by the taxis. He deserves our best acknowledgments, inasmuch as he has insisted on a method which, I verily believe, might have been successfully adopted in many of the cases which have been subjected to the severer operation. For the cause of suffering humanity, therefore, I am happy that I can offer my testimony to the superiority of the mode of proceeding Mr. Hunt has recommended.

If the explanation of the physiological principles on which the misfortune depends be correct,—namely, the congestive state of the veins, then we must admit, consequently, the impossibility of returning the venous blood or other contents of the hernial tumour by a *hasty* trial of compression. The reduction of strangulated hernia by the taxis is a *slow* process, but speaking from my own experience, it is always possible. He is wanting in patience or practical tact who does not succeed when called in to a case before acute inflammation has supervened. The directions for the reduction of hernia are usually absurd. To talk of kneading the tumour is mischievous,—of first "pulling out" further the contents is impossible, or if not impossible, only adding to the existing evil. Lastly, to limit the

taxis to "a quarter or half an hour," is inexcusable haste. I confess, however, that formerly I have followed this plan to my disappointment; latterly, in such cases, I have used continued compression with one or both hands, in the direction of the ring, for the space of from one to two hours. In this way I have not failed to diminish the size of the hernia, and to return the prolapsed viscera. By such means I have gained the confidence and esteem of my patient.

The greater operation is, I grant, in the eyes of the ignorant, a more brilliant affair. It is talked of through the neighbourhood, and it is understood that the sufferer has been rescued from the very jaws of death, by the skilful employment of the knife. Nevertheless, we ought no longer to refuse to admit a fact stated by your correspondent, amounting to this,—that where an enterocele, epiplocele, or an entero-epiplocele, can find an exit from the abdominal cavity, *cæteris paribus*, it can be replaced by the taxis. If indeed the hernial tumefaction, by accident or neglect, has too exalted a sensibility to the manuduction of the surgeon, small doses of tartarized antimony may be frequently given, or other means used for the purpose of subduing inflammatory action, before or during the taxis.

A short time ago a lady, owing to the weakness of the spring of her truss, and in consequence of a long walk, had an inguinal hernia so far descend, or so swollen, as, with all her efforts, to be unable to return it. On visiting her I found her in a most uncomfortable state,—with great anxiety in her countenance, sickness, pain in the epigastrium. It was a difficult case, for the hernia was tense, and apparently unyielding, yet steady continued pressure for the space of an hour and a quarter, by degrees lessened the volume, and at length, with a sudden gargling, the sac, with its contents, in an instant passed into the abdomen.

I am, Sir,

Your obedient servant,

J. PAXTON, M.D.

Rugby, February 18, 1848.

CASES OF PLACENTA PRÆVIA, WITH OBSERVATIONS.

By EDWARD RAY, Esq., Dulwich.

(Read before the South London Medical Society, January 6th, 1848.)

Feeling that in difficult and fatal parturition, no class of cases are attended with greater danger to the life of the mother and the child, and that none perhaps are more awful, or occasion more anxiety even to the practitioner, than those of placenta prævia, I am induced to bring before the notice of this Society, the following cases, in which the placenta was either expelled or removed from the uterus, when the patients were exhausted by the loss of blood, and were still bleeding, with the effect of causing the immediate cessation of the hæmorrhage; and that after an interval, (which allowed of the free use of restoratives,) the patients, without any further loss of blood, were delivered of their children by uterine action.

CASE I.

Mrs. Duffield, residing in a lone cottage in the midst of some fields, aged 27, the mother of one child, and seven months advanced in pregnancy, was, on the 8th of April, 1847, attacked suddenly, and for the first time, with hæmorrhage from the uterus, without pain, about 4 p.m. The hæmorrhage increasing, and being alone, she determined to go to a man working at some distance (about 300 yards,) and send him for assistance. On walking, the hæmorrhage increased, and with it her alarm; she, however, effected her object, and has since described "the blood as if pouring from her" on her way back. Before regaining her cottage, she stated that she could not see, and with difficulty succeeded in groping her way by palings, &c., to the cottage door, and from thence to the bed on which she fell. I arrived about five o'clock, and found her lying partly on the bed, and her clothes dyed in blood: she was blanched, cold, almost pulseless, unconscious, and blood continued to drain from her. Brandy was freely given, and after examination one drachm of powdered ergot in form of infusion. On examination the os uteri was found dilated, and the placenta bulging through it: anteriorly the distended membranes could be reached, and a foot detected; the membranes were then ruptured, and the foot brought down. Hæmorrhage continued; slight uterine pains occurred; pressure was applied over the uterus, *which was firm*, and the child, a female, delivered, still-born. On examination another fœtus was detected; the hæmorrhage continued, and the placenta occupied the same position: with some difficulty I reached and ruptured the second bag of membranes; the fœtal head descended, and with the gush of liquor amnii the placental mass was expelled, which proved to be a double one, and remained connected by one cord to the child unborn. The hæmorrhage now (half-past five,) ceased, and although uterine pains did not recur for two hours at least, and the delivery of the second (a still-born female,) was not completed until after half-past eight, *there was no return of it*. After the expulsion of the child, the uterus did not contract firmly for some time, but I could detect no unusual hæmorrhagic discharge; steady pressure was at first kept upon the uterus with the hand, and afterwards by means of a pad and bandage firmly applied. Her temperature improved with her pulse, after the free administration of brandy in gruel, and she was partially conscious during delivery. After delivery she suffered from hydrosis, and this was followed by general anasarca, accompanied throughout by defect of vision, from which she eventually recovered, and has since given birth to another child. It is impossible to form any idea of the quantity of blood lost in this case; her gory track was more than readily to be traced, and the cottage floor was covered with blood.

CASE II.

Mrs. Duke, aged 28, four feet ten inches in height, and possessing a small rounded pelvis, had given birth to two small living female children at the full period, after long and severe labours; had aborted once at the third month, and had expelled an uninpregnated ovum, after having obscure symptoms of pregnancy for five months. She was in the last month of utero-gestation when I was summoned to her, at half-past 4 a.m. of October 14th, 1847. I found her upon the bed, lying partly upon the left side and the abdomen; unconscious; ghastly pale; cold; pulse scarcely perceptible; sighing occasionally; breath of death-like coldness, and occasional jactitation

of the arms. The clothes and bedding were saturated with blood; blood was found upon the floor; and a chamber-vessel by the side of the bed contained more than five pints of coagula. (This was ascertained afterwards by measure.) A wine-glass of gin was immediately given: brandy procured, and a dessert-spoonful given in a little warm gruel frequently.

On examination blood was found oozing from the vagina, which was filled with coagulum. The os uteri was fairly open and dilatable: within it, and completely surrounding it, was found the placenta. No sensation of fluid within the uterus could be detected, and the firm head of a fœtus could be distinctly felt through the placenta. The *uterus* through the abdominal parietes was *found firm and globular, and remained steadily so, without any evidence of uterine pains:* no fœtal movement could be detected, and, having no stethoscope with me, the position and state of my patient prevented my endeavouring to ascertain the existence or non-existence of the child. Without altering the position of my patient, I determined upon immediately removing the placenta, which I found attached to the anterior part of the neck of the uterus, the posterior and larger portion of the placenta being already detached, and separated from the uterus by coagulum. The separation was readily effected by passing the left hand between the uterus and placenta posteriorly, then gradually rotating the hand to the right, keeping the dorsal surface of the fingers firmly pressing against the uterus, and the margin of the placenta within their palmar surface, so that it was readily removed after its detachment by bending the fingers and withdrawing the hand. Some portion of the membranes being fixed between the head and pubis yielded during extraction, and remained behind. Hæmorrhage continued during the removal of the placenta, but ceased with its removal at 5 a.m., and no coagula formed afterwards in the vagina. The placenta was entire, of usual size; coagula were adhering to a considerable portion of its maternal surface, and its structure was to all appearance healthy. The cord was not tied nor divided until some half hour after the removal. I could distinguish no pulsation in it, but found the umbilical vein enormously distended.

The poor woman was now warmer; somewhat conscious; pulse more perceptible, though very feeble,—rapid, and not to be accurately counted; free from pain and hæmorrhage. The *uterus continued firm and globular;* and, upon examination, a very firm fœtal head was found resting upon the open os uteri in the natural position. The abdomen (which had until now been supported by hands,) was encircled by a broad bandage; and as the patient dosed at intervals, the brandy and gruel was only occasionally given, and in smaller quantities.

About half-past 7, slight uterine pains commenced, and gradually increased; the temperature of the patient was good; the strength of the circulation had improved, and the radial artery communicated the characteristic vibratory sensation of the hæmorrhagic pulse, the number of beats varying from 140 to 150 in the minute; no return of hæmorrhage.

At half-past 8 pains were frequent, but not strong enough to be effective; the firm fœtal head remaining fixed in the brim of the pelvis, and resting on the dilated and dilatable os uteri. One drachm of powdered ergot was given in the form of infusion, and speedily increased the strength and frequency of the pains, but without affecting the position of the fœtal head. Shortly after 9 o'clock, not deeming it prudent to tax further my patient's powers of endurance, I opened the head with a strong pair of scissors, and, with very little aid in the way of traction, the head shortly passed into the cavity of the pelvis, and was expelled with a portion of the membranes *by the uterine efforts* about 20 minutes past 10—more than five hours after the removal of the placenta. There was no hæmorrhage after the labour: indeed, after the removal of the placenta, the fingers were not rendered more sanguineous than usual by the examination (excepting, of course, the effect of opening the cranium,) and the only napkin I kept applied was soiled, not sodden, by the discharge. The child (a male,) was dead, well-formed, of full size, and livid.

After the labour, my patient was much better than could have been anticipated; *the uterine action appeared to have rallied her most effectually;* the surface of the body was not only warm, but moist; pulse 136, of vibrating character. Though not disposed to speak when addressed, she was perfectly conscious, and the uterus remained firmly contracted. The abdomen was firmly supported, and the position directed to be maintained until my next visit.

It is sufficient to state that this poor woman steadily improved; the pulse gradually diminished in frequency, and lost its character. The confusion in her head consequent on the loss of blood was her only complaint, and this, which she compared "to the constant noise and bustle of a railroad station," slowly subsided. She suffered but little, and for a short time, from the distension of the mammary glands, or consequent constitutional irritation. After this, as after former labours, she had but little lochial discharge, and the after-pains were scarcely recognized. She was allowed light broths and milk, with her gruel and arrow-root, from the first, and, after a few days, tonics were prescribed, and the diet further improved.

Her after-statement was, "that there had been no previous hæmorrhage; that she went to bed well, and was awoke before 4 o'clock with an urgent desire to pass water; something escaped, which she supposed to be urine, before she could gain the vessel: on seating herself, there was a sudden gush of she knew not what; she felt faint, and knocked." It appears that a female in the house found her upon the vessel, leaning against the bed, insensible, and, with assistance, placed her as I found her.

Remarks.—I do not advocate the removal of the placenta in all cases of unavoidable hæmorrhage, but I am able to add my testimony to the comparative safety of the practice, as far as the mother is concerned, in such cases alone as those related; and I confess, that until the occurrence of my first case, I did not attach to the opinions of the late Mr. Kinder Wood, Dr. Simpson, and Dr. Radford, the importance that I now feel they deserve.

I was induced to adopt this practice in the second case—

1st. From having witnessed in the former case the immediate cessation of the hæmorrhage on the expulsion of the placenta.

2nd. From believing that increase of exhaustion from further loss of blood, or from emptying the uterus, might probably be fatal.

3rd. From the known difficulty in turning, the uterus

having lost its fluid contents, and being in a state of *tonic contraction* around the body of the fœtus:

4th. From the impression that the delivery would be difficult, even could turning be accomplished, from the firmness of the head, presumed sex of the child, and the knowledge of former severe and lengthened labours when the children were small, and females.

5th. From viewing the tonic contraction (or firmness,) of the uterus as favourable to the prevention of hæmorrhage after the removal of the placenta.

The source of the hæmorrhage (whether it proceeded from the uterine arteries, sinuses, or from the opened cells on the maternal surface of the placenta, individually or collectively,) was *maternal*, and was derived principally from the venous system, as the uterine arteries, from their size, tortuosity, and contractility, could not produce those awful gushes. On considering the number, size and free communication of the uterine sinuses with each other, tracing them through the uterine plexus to the internal and common iliac veins, and finding that these veins are not supplied with valves, I can readily understand hæmorrhage to any amount, though the placenta was but partially detached, the uterus being in an *atonic* state.

The principles of treatment must be directed to restraining the hæmorhage and supporting the vital powers of the patient.

To restrain the hæmorrhage, the object must be to promote and ensure uterine contraction. The means employed may differ, but they tend to the same end. When the os uteri is undilated, the introduction of a sponge tent and plugging the vagina, mechanically assist to restrain the hæmorrhage, but tend physiologically to induce uterine contraction, as in the induction of premature labour. The rupture of the membranes brings the firm body of the fœtus into more direct contact with the lining membrane of the uterus, and induces uterine contraction, (as in the induction of premature labour, or the effect of a foreign body within the uterus,) *affects the course of the sinuses, and causes pressure upon the hæmorrhagic source, the placental pad intervening.* Should hæmorrhage still continue, the uterus being in a state of *tonic contraction*, it appears to me that the removal of the placenta allows of still further contraction of the muscular structure of the uterus, and *direct pressure* upon the open vessels. My impression is that it would be madness to *remove the placenta, or to deliver after turning, the uterus being in an atonic state*; that to *deliver or empty the uterus* of its contents, with safety to the mother, *clonic contraction* should be present, but that *tonic contraction* is sufficient to restrain hæmorrhage after the removal of the placenta, the *fœtus remaining in utero.*

Uterine contraction (tonic and clonic,) might be induced by external friction or pressure, mammary irritation, enemata, ergot, galvanism, &c.,; but in cases of extreme exhaustion from hæmorrhage, I am disposed to believe that the *most powerful excitant of motor power is the presence of the firm fœtal body within the uterus, and that the induced uterine action after the removal of the placenta is not only beneficial in causing the natural expulsion of the child, and consequently diminishing the risk of after-hæmorrhage, but is also of the greatest value in producing reaction from the effects of the previous hæmorrhage*, the vital powers to be supported by the free administration of stimulants, with nutriment.

In conclusion I question the propriety of tying the cord in these cases, as children are occasionally born alive when following the placenta, and recommend the employing of an inverted bowl or small bason, with a folded napkin intervening, to ensure pressure over the uterus, as suggested by Mr. Harvey, of Castle Hedingham, to prevent after hæmorrhage.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, MARCH 8, 1848.

It will be in the recollection of the members of the Provincial Medical and Surgical Association, that at a conference which was held by the Home Secretary with a deputation from the Association, it was suggested by the Right Honourable Gentleman that the several corporate bodies and other parties interested in the subject of medical legislation should endeavour to come to some arrangement amongst themselves on the questions under consideration. A conference was accordingly proposed by the Council of the Association, but which from an indisposition manifested by certain parties to enter into it, was at that time laid aside. Meetings have, however, lately taken place among certain sections of the profession, which hold out a promise of favourable results, and the Central Council of the Association having received information of these meetings, deemed it right, therefore, at once to appoint a deputation, to confer with the Royal College of Physicians, in accordance with the courteous intimation which had formerly been received from that body.

The object of this deputation was to lay before, and explain to, the College, the principles adopted and hitherto acted upon by the Association, and at the same time to obtain from the College authorities more full information as to what was now contemplated on the subject of medical legislation by the several corporate bodies of the profession in England.

It is with much satisfaction that we are enabled to announce that many of the difficulties which formerly beset the question of medical legislation are removed, and prominently among them we may state that the demand for a

separate incorporation of the large and influential body of the General Practitioners is likely to be acceded to; and that the establishment of such an incorporation forms a prominent part of the measures in contemplation.

Another of these measures is the formation of a competent central governing body or council, for the regulation of all matters relating to medicine; and a protective measure which renders it a fraud, and punishable as such, for any person to assume the titles of medical practitioners, unless duly authorized by law so to do, is also to be brought forward.

We are, however, on the present occasion, chiefly desirous to direct the attention of gentlemen practising in the country as physicians, to that portion of the proposed measure in which they are especially concerned. The London College of Physicians will of course take care of their own body; the College of Surgeons of England may be expected to do the same by their own members; and the general practitioners will find that their interests have been attended to by the National Institute of Medicine, Surgery, and Midwifery, which will, we presume, form the nucleus of the future College or incorporation. The Council of the Provincial Association, however, feel deeply interested in the welfare of all provincial practitioners, of whatever grade or denomination; and while they are quite willing to believe that the interests of certain of them will be attended to by the Corporations and the National Institute, they will feel themselves bound to exercise a vigilant inspection over what is going on. As the provincial physicians have no voice in any of these bodies, the Council deem themselves especially called upon to advise those gentlemen of what is now intended in relation to the position which they are to occupy in the legislative measures now under consideration.

With this view then, we extract the following clauses from the intended Charter of the Royal College of Physicians of England:—

Clause 2.—That the said Corporation shall consist of Fellows and Associates, [or Members,] including a President and Council, four Vice-presidents, four Censors, a Treasurer, and a Registrar.

Clause 3.—That all the present Licentiates of the said Corporation shall be Associates [or Members] of the said Corporation.

Clause 4.—That each of the present Extra-Licentiates of the said Corporation shall be admitted an Associate [or Member] of the said Corporation, on the production to the said Censors of the said Corporation, of testimonials of character and professional qualification, which shall be satisfactory to the said Censors, and on passing such examination before the said Censors as shall be required by, and shall be satisfactory to, the said Censors, and on his paying to the said Corporation a fee of £25 exclusive of the stamp duty.

Clause 5.—That every person now practising as a physician in England or Wales, and who shall have taken the degree of Doctor in Medicine at any University in the United Kingdom of Great Britain and Ireland, after regular examination, (previously to the 1st day of January, 1842,) and who shall have attained the age of 30 years, and who shall not be engaged in the practice of pharmacy, shall at any time within twelve calendar months from the acceptance of these, our letters patent, by the said Corporation, in the manner mentioned in the Act of Parliament, hereinbefore stated to have been passed in the present year of our reign, be admitted an Associate [or Member] of the said Corporation, without any examination, on the production to the said Censors of the said Corporation, of his diploma, and of such testimonials of character and professional qualifications as shall be satisfactory to such Censors, and on his proving himself to be of the said age, and on his assuring such Censors that he is not engaged in pharmacy, and on his paying to the said Corporation a fee of £25, exclusive of the stamp duty.

The Clauses here quoted speak, perhaps, sufficiently for themselves. Every physician of six years standing, who is a Doctor of Medicine of a British University, and of the required age, may become an Associate, or Member, of the College, and entitled to all the privileges of membership. There is, however, a point in Clause IV. which demands notice here. It is well-known that many gentlemen now practising in the country as physicians, under the extra-license of the College, are not in possession of the degree of doctor of medicine, which would entitle them to enter the College as associates under Clause V. The call upon these gentlemen to produce testimonials of character and professional qualification, is, we presume, a provision which has become necessary, from the loose and reprehensible manner in which the Elects of the College have at various times acted, in reference to the granting of the extra-license, whereby they have admitted some unworthy and ill-qualified persons into their body, and done especial injustice to the very many highly respectable gentlemen who have been induced to accept of this license.

The payment of an admission fee in either case,—that of the extra-licentiate, or that of the physician, hitherto not a member,—is just, as privileges, the same as those to be enjoyed by the former licentiates are granted to both;

but it is a question whether the specified amount of the fee is not too great to require from a large number of gentlemen, very many of whom have established a high reputation for themselves independent of the College, who will confer honour on any body to whom they belong, and who may be well contented to remain as they are.

In reference to the Fellowship, it is known that the old practice of confining it chiefly to the graduates of Oxford and Cambridge has for some years been altered. Of late the more liberal plan of selecting from among the Licentiates a certain number of gentlemen of reputation for professional scientific or general acquirements has been followed, and we have pleasure in admitting that the selection has been for the most part judiciously made. It is now proposed that the Fellows shall for the future be elected from among the Association by the general body.

Notice.—It is particularly requested that, gentlemen practising as physicians in the provinces, will communicate their opinion in reference to the subject of the preceding observations to the Council of the Provincial Medical and Surgical Association, in order that the views of provincial physicians on the Clauses IV. and V. of the proposed new Charter of the College may be ascertained.

ROBERT J. N. STREETEN, M.D.
Secretary to the Association.

Reviews.

On Indigestion: its Pathology; and Treatment by the Local Application of Uniform and Continuous Heat and Moisture. By James Arnott, M.D., Physician to the Brighton Dispensary. London: 1847. 8vo. pp. 107.

There are few who are much engaged in practice, who have not had frequent reason to be disappointed with the methods commonly followed of using warm and cold applications in the treatment of disease. Nothing, for instance, can be more unsatisfactory than the ordinary mode of applying cold to the head in fevers or in certain forms of cerebral disease. "There is a vast difference," says Dr. Graves, in his 'Clinical Medicine,' "between a thing being done and its being well done: so it is with regard to cold lotions; so difficult is it to ensure their proper application, that I have entirely given them up in hospital practice, and rarely order them in private. I have been induced to abandon them in conseqence of witnessing so many instances in which my directions were neglected, and consequently the cerebral congestion was augmented by their malapplication." And again, "In fevers, I can say positively, that in the majority of cases they are certainly injurious, *as usually applied.*" In these observations we most entirely concur and have now for some time been in the habit of following the advice of Dr. Graves in withholding cold in such cases, and in recommending sponging with warm vinegar and water, or the employment of folds of linen wetted with the same, instead.

It is to point out a means of remedying this defect and uncertainty in the local use of cold, and equally also of heat, and to recommend his improved method of employing heat and moisture in the treatment of disease as a powerful means in the cure of indigestion, that Dr. Arnott has published the short treatise which forms the subject of this notice.

The first section of the work is devoted to general observations on the local application of heat and cold in the treatment of irritative and inflammatory diseases. In the second section is considered the local and *uniform* application of heat with moisture in the treatment of indigestion. In the third and last section is given a description of the apparatus which he makes nse of, and directions for its management.

The great principle for which Dr. Arnott contends, is the importance of uniformity in the temperature employed, whether above or below that of the part to which it is to be applied; and to produce this he has devised an apparatus by which a constant current of water, at the temperature required, is transmitted over the part. This apparatus consists essentially of a reservoir containing some gallons of water, heated or cooled to the degree wished for; a hollow water-proof pad or cushion, capable of holding a sufficient quantity of water, to be applied in close contact with the part to be subjected to the treatment; and a vessel for receiving the waste water. The reservoir communicates by a flexible tube with the water-cushion, and the latter by a similar tube with the receiver. By raising the reservoir to an appropriate height, a current may be thus made to pass from the reservoir through the supplying tube into the cushion, and thence again to be carried off through the waste pipe.

It is obvious that in this manner, with due precautions in the adaptation of the instrument, in the regulation of the temperature of the water, and of the pressure, any desired amount of heat or cold within certain limits, may, be locally and uniformly applied.

For precise directions on this point, for the construction and detailed description of the apparatus, and for directions as to its use in particular diseases, and especially as a topical remedy in indigestion, we must refer to the work itself.

Dysphonia Clericorum, or Clergyman's Sore-Throat: its Pathology, Treatment, and Prevention. By James Mackness, M.D., Member of the College of Physicians, London, Consulting Physician to the Hastings Dispensary. London: 1848. 8vo. pp. 125.

This unpretending volume is devoted to the consideration of a not unfrequent, and when it occurs with severity, a very troublesome and serious affection. The clergyman's sore-throat, as Dr. Mackness terms it, would seem to owe its origin to excessive, irregular, or forced action of the organs of speech; and the disease attacks not only clergymen, but also members of the bar, and of the senate, professional singers, and all who are in like manner called upon to make similar exertions. If not early attended to, and the appropriate treatment (of which absolute rest forms a most essential part,) had recourse to, the consequences are very prejudicial, inducing permanent incapacity, or even in some cases laryngeal phthisis and death.

After two chapters on the anatomical structure of the parts concerned in the disease, the author proceeds to a consideration of the causes, the pathology, symptoms, prognosis and treatment, and prevention of the disease. In the course of these observations, frequent reference is made to a treatise, by Dr. Horace Green, of New York, on "Follicular Disease of the Pharyngo-Laryngeal Membrane," who describes it as an affection of the mucous follicles, attended with secretion within the follicles, or infiltration into the submucous tissue, of tubercular matter, or of a substance resembling it. Dr. Green's work, however, appears to refer to a more severe form of disease than what is usually seen in this country; and for information on the affection which more commonly comes under our notice, and its management, the work before us will be more advantageously consulted. The treatment recommended by Dr. Mackness is judicious, but it is obvious that the interdiction of all over-exertion of the voice, and in cases of duration or severity the injunction of absolute rest, must form a most important item in the means employed.

To clergymen especially, many of whom are accustomed to raise the voice above its natural pitch in reading portions of the service, the following opinion of a high authority on the proper use of the voice (Mr. Macready, the actor,) may afford some useful hints:—

"Relaxed throat," he observes, in a letter addressed to Dr. Mackness, "is usually caused, not so much by exercising the organ, as by the kind of exercise, that is, not so much by long or loud speaking as by speaking in a *feigned* voice. I am not sure that I shall be understood in this statement, but there is not one person in, I may say, ten thousand, who, in addressing a body of people, does so in his natural voice, and this habit is more especially observable in the pulpit. I believe that relaxation of the throat results from violent efforts in these affected tones, and that severe irritation, and often ulceration, is the consequence. The labour of a whole day's duty in a church is nothing, in point of labour, compared with the performance of one of Shakespeare's leading characters, nor, I should suppose, with any of the very great displays made by our leading statesmen in the Houses of Parliament. I am confident as to the first, and feel very certain that the disorder which you designate as the clergyman's sore-throat is attributable, generally, to the mode of speaking, and not to the length of time or violence of effort that may be employed. I have known several of my former cotemporaries on the stage suffer from sore-throat, but I do not think, among those eminent in their art, that it could be regarded as a prevalent disease."

It will be important, therefore, for the medical practitioner, to recommend to persons suffering from, or liable to, this affection, whether in continuing to follow their profession or in resuming its duties after a temporary cessation of them, to be most careful at all times to read or speak in their natural tone of voice. For the fuller development of the principles necessary to be followed in the general treatment of the more severe forms of the disease, we have pleasure in recommending the work before us.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

CASE OF SEVERE AND EXTENSIVE BURN,

WITH Remarks in reply to Mr. Crompton's Questions.

By John Gabb, Esq., M.R.C.S., & L.A.C., Bewdley.

On February 13th, 1847, James Palmer, aged 5 years, was extensively burnt by his clothes taking fire whilst left alone in the house. I arrived a few minutes after the accident, and when the remaining portion of clothes was removed, found the burnt surface occupying the upper two-thirds of the fore part of the right thigh, extending up the side of the abdomen to the thorax, over about a third of the surface of the right side of the thorax, surrounding the shoulder and the whole of the arm down to the wrist, the palmar surface of the thumb and all the fingers being more or less injured. Two or three small blisters were also found on the head. I had the child put directly into a warmed bed, lying on his left side, and applied flour by means of a common dredger over the whole injured surface. The flour gave such relief that the child almost immediately ceased to cry, and began to point with his left hand to parts where he felt desirous of having more applied. I prescribed a mixture of Liquor Ammoniæ Acetatis, Tinctura Hyoscyami and Mistura Camphoræ, a dose to be taken every two or three hours, for the first day or two, and ordered the flour to be applied at intervals wherever moisture appeared, for a week, taking care to have plenty in the axilla, and between the burnt surfaces of the arm and side.

During the first eight days the child was not tortured by any other dressing than the flour, and appeared to suffer but little pain after the first smart was relieved;

he was, however, much depressed, had an exceedingly quick pulse, with considerable thirst, and little if any sleep for the first forty-eight hours after the accident, within which period I believe one torturing dressing would have killed him. On the seventh day, the discharge having become offensive, I applied a soft bread-and-water poultice over the whole, at bed-time, and in the morning on removing the poultice, the crust formed by the flour came off with it, exposing over the greater part of the injury healthy granulations; but on the arm were some extensive sloughs not quite detached.

I now dressed daily the whole injury with fine lint, wetted in warm water, and so covered it with oiled silk as to keep it moist. In a few days the sloughs had all separated, and from this time, indeed from its commencement, the progress of the case was very satisfactory, nothing being applied from first to last but flour and wetted lint.

In a case of scalding of both feet and ankles in a child two years of age, I have found the same plan of treatment equally satisfactory, and even more so, if possible.

Remarks.—The notes taken of this case at the time of its occurrence, were not intended for publication, or I should have been more particular in the observance of dates; I have no memorandum of the last time of dressing, but the cure was complete in about two months. The case has been brought forward merely as an illustration of the efficacy of the most simple of remedies, and a remedy which only requires to be tried to be approved. It may serve also as an introduction to a few observations on the questions proposed in the Journal to the profession, on the treatment of burns and scalds.

1. Stimulants are no doubt useful as local applications in burns of the first degree, where we have only an erythema without vesication, and where the injured surface is not of very large extent; but in all other degrees of the injury, stimulants topically must do more harm than good, the *system* suffering from over-stimulation already. If stimulants be used in any other degree of burn than the first, they should be applied internally, with a local cooling application, such as flour. Even in burns of the first degree, (although the stimulating plan of treatment is so commonly followed, especially by non-professional persons, as when they hold the injured part to the fire, &c.,) I prefer the cooling system as most rational, and as likely to moderate, rather than increase, the constitutional irritation, which sometimes arises from this degree of the injury, particularly in delicate subjects, in whom a small extent of surface injured will occasionally give rise to much general disturbance.

2. Cool applications are always admissible, even in burns of large extent, but a distinction must be kept in view between *cool* and *cold*. Flour might be safely applied in a case of the greatest nervous depression, where ice, or an evaporating lotion, would probably soon render any other application quite unnecessary. The value of flour can only be appreciated by those who have used it; it is more valuable than cold water in burns of small or great extent.

3. Liston preferred flour.

4. Sedatives and stimulants, which allay nervous irritability, determine to the surface, prevent internal congestions, and by so doing ward off inflammation, &c., selected according to the indications of each particular case.

6. Can a cicatrix be prevented where the cutis or its surface has been destroyed? It certainly cannot be prevented where the injury extends through the true skin, but much may be done towards preventing the contraction of the cicatrix, and the consequent deformity, during the process of healing, even if the injury has been deep and extensive; but before speaking of a rational method of treatment with this object in view, I must briefly refer to the process of healing by granulation. What are granulations? They are temporary organs to serve a temporary purpose; the *vis medicatrix naturæ* raises them to perform a certain work, or rather to enable her to perform it, for the granulations are but the scaffolding by means of which the new structure is to be raised, and when the work is completed, they are removed. According to such view of the process of granulation, there must be a contraction of the cicatrix proportionate to the space occupied by the little temporary organs before they were removed, in order that the new structure be sufficiently compact; and does not this point out the impropriety of speaking so confidently of exuberant granulations, and of suppressing them so frequently? Healthy granulations should stand out well above the surrounding integument, if there is not to be a contracted cicatrix; if they are large and flabby, and pale coloured, support the strength of the patient, raise the constitution up to its work, and let not the work be cut down to the diminished powers of the constitution by the application of caustics. If caustic, or anything approaching to it, be used, as the sulphate of copper, it should only be applied to the *outer margin* of the granulating wound, the granulations in the centre being left to complete their work, until the integument encroaches immediately upon them. Nothing but deformity can be gained by hastening the cicatrization of a wound,—by repressing what are too frequently called exuberant granulations, supposing the process capable of being expedited by such means. In the case given above, everything was left to nature and wetted lint; no caustic of any kind was employed from first to last; and it was really wonderful to observe, day by day, the granulations pulled down to its own level by the surrounding integument.

With regard to the questions to which I have not directly referred, it would be only extending the length of this communication to answer them. Two things I would particularly insist on,—*the value of flour*, as the application for the first few days, and the *consequence* of *too frequently repressing granulations*,—viz., a *contracted cicatrix*. All statistical observations, &c., I leave to those who fill situations in hospitals, and have the best opportunities of making them; and would only add, that I consider the "simplicity of a remedy the measure of its perfection."

February 23, 1848.

COMMUNICATIONS.

[The following communications have been forwarded by Mr. Crompton.]

From T. Ogier Ward, M.D., Kensington.

Before I answer the "queries" respecting the treatment of burns, I trust I shall not be trespassing too much if I give a short history of the introduction of cotton as a remedy in burns and scalds, extracted from a paper read by myself before the Westminster Medical Society, in 1828, when a student at St. Bartholomew's Hospital, where, by the kindness of the late Mr. Earle, I was permitted to make some experiments upon its use, which led, as the nurses have recently informed me, to its adoption in that institution.

"The treatment of burns and scalds by raw cotton was discovered by accident in the United States of America, and has been described by Mr. Dollam, in 'Potter's Medical Lyceum,' and by Professor Gibson in his work on surgery. From America it was introduced into the Belfast Hospital, and from thence into the Royal Infirmary of Glasgow, in both of which institutions it has superseded every other mode of treatment. Having witnessed and tested its advantages while a dresser at the latter place, under Dr. Young, in several cases, (some of which are described in a letter from Mr. Plymsoll to Dr. James Johnson, in the Fasciculus of the 'Medico-Chirurgical Review,' of March 8th, of the present year, 1828,) I mentioned this plan of treatment to Mr. Earle on my return to England, and he kindly permitted me to use it in the cases I am about to mention. The wife of the clerk of Welbeck Chapel, has performed so many cures with raw cotton for the last eight years, that there is scarcely a case of burn among the poor of that district that does not come under her care."

The cases alluded to were six in number.

In the first, a child aged 4 years, there was a scald on the breast, eight inches by five, covered with large vesications. Turpentine had been applied, but it was removed to make room for the cotton. In eighteen days after admission the child was made an out-patient, with only one small sore remaining, where the largest vesicle had been.

In the second case, a child aged 7, large vesications extended from the middle of each forearm to the fingers' ends, the cutis being deadened from the axilla along the fore and inner part of the upper arms, from a burn. The cotton was applied and changed as often as it became soddened by the discharge from the sloughing parts, but it was allowed to remain over the vescications as the sloughs had not separated. On the fifteenth day the cotton was removed by the dresser and not re-applied, to make way for poultices. At this time the other parts were healed; but the sloughing portions, which were dressed with resinous ointment on lint, after the cotton was relinquished, were not cured above two months afterwards, when the paper was drawn up.

In the third case, a child, aged 5, had a deep burn of the right arm and axilla, from which the sloughs had come away by the use of poultices before I saw them. The sore had a healthy granulating appearance, and the cotton was applied together with a splint to prevent contraction of the sore upon the upper arm. After five applications the sore was healed except at the bend of the arm and in the axilla, when unfortunately no more cotton could be procured, and as the child could not bear the splint without the cotton, which acted as a pad, the sores were dressed with what little cotton was left. The splint being disused, the forearm became contracted as the sore healed, and the cotton being now exhausted the splint was re-applied, the sores being dressed with simple cerate. But the child's health had now begun to suffer from his confinement, and his bowels became disordered. The sores which had healed broke out again and could not be brought to assume a healthy appearance; and after he had remained in this state about a fortnight he died rather suddenly, from inflammation of the stomach and duodenum.

In the fourth case, a child, aged 1 year and 9 months, severely scalded on the face, neck, and shoulders, by melted fat, I applied the cotton February 12th, and on March 5th, he was made an out-patient, having only one small spot unhealed. He died suddenly, March 28th, within an hour of the last case, and from the same cause, viz., inflammation of the stomach and duodenum, with intussusception of the ileum and effusion into the chest. The sores, however, were quite healed before his death.

The fifth and sixth cases were severe scalds, with vesications. The former was healed in a week by a single dressing with cotton. In the latter case, after the first dressing with cotton, the sores were poulticed, and then dressed with resinous ointment for want of cotton; but as soon as more cotton was procured, it was re-applied, and the patient was discharged cured in less than three weeks.

One of the cases mentioned in Mr. Plymsoll's letter, and treated by me in the Glasgow Infirmary, was remarkable for the severity of the burn, and the completeness of the cure. The patient had buried his foot up to the ankle in a burning mass of soda or lime, which caused the skin of the instep, a considerable depth into the extensor tendons, and down to the bones of the fourth and fifth toes, to slough away; nevertheless, after the two toes had been amputated, the whole sore healed over without any appearance of a cicatrix, the skin, to use Dr. Young's expression, being renewed like that of a young child.

In another case the whole of the back had been burnt by a mine explosion, and was one immense sore. The man was wrapped in cotton, and though in torture previously, expressed himself as free from pain immediately after its application. This patient died exhausted by the profuse discharge, and my memory does not serve me as to the *post-mortem* appearances.

In other superficial burns and scalds the cotton answered admirably, adhering firmly till thrown off like a skin by the formation of the new cuticle beneath.

Except in the use of paint, which I have not tried, my practice and experience coincides entirely with that of my friend Mr. G. Edwardes, of Wolverhampton, to whom I believe I communicated the cotton treatment when I settled there in 1831. I have also found the cotton extremely useful to relieve the smarting of blisters and other cutaneous affections; and I have at this time a

young lady under my care to whom I have applied the cotton with complete success for an extensive eruption of herpes zoster, attended with the usual painful tingling and burning sensations. A single application has taken away all the pain, and apparently prevented the rupture of the vesicles and the consequent sores.

I will now reply to the queries *seriatim*, as far as I am able.

1. Extensive burns and scalds are attended with so much depression and chilliness, amounting to complete rigor, that until I can procure cotton, I should certainly use stimulants, both outwardly and internally.

2. My own experience of the extreme pain of cold applications would prevent my using them in small burns, and in large ones they are too depressing to be admissible.

3. Cotton has the advantage of flour in this respect,—that it does not form a harsh dry crust ; but flour is very cooling when the burn or scald is of the slightest kind, by increasing the surface for the radiation of the abnormal heat.

4. Spirituous stimulants, proportioned to the age, &c., of the patient, and the state of the case.

5. The least moveable and most fleshy parts heal most readily.

6. Where the cotton has been *properly* used, I have not remarked cicatrices.

7. Inflammation of, and effusions into, the chest, and ulcerations of the upper part of the intestinal tube.

8. From my experience in the cases already mentioned and others, I always give a guarded prognosis in *deep* burns or extensive scalds.

10. To keep the patient and the part warm and *covered*.

11. After the first depression has been removed, the diet should be nourishing, but not stimulant, for fear of internal inflammation.

12. Already answered.

Though my experience is altogether in favour of the cotton treatment, yet I ought to mention that it is attended with some objections, particularly during summer, first from the fœtor of the discharges attracting the flies, which, breeding maggots, excite the horror of the friends, at the same time that they are sickened by the stench. Hence it requires some firmness on the part of the medical attendant to induce perseverance in the treatment. Again, the confined and fœtid pus has had in some instances an injurious effect on the patient, where the sodden portions of the cotton have not been removed frequently ; and this operation requires some little dexterity, to avoid tearing off the cotton where it has become adherent to the newly-formed cuticle, which bleeds at the slightest touch, and then is more difficult to heal than at first.

From William Strange, M.D., Bridgnorth.

As a member of the Association, I feel in duty bound to furnish my experience in the matter of "burns and scalds." Since I have resided here my experience of both has been *nil ;* but during a residence of six years in Lancashire, close proximity to numerous coal mines gave me the opportunity of frequently witnessing cases of the former in every degree of severity. In my opinion our actual knowledge of disease will be extended quite as much by the members of our profession abstaining from giving any opinion upon a practical subject, except such as they may have formed from *an unavoidable induction from a sufficiency of facts*, as by the more general course of bringing prominently forward every case which may seem to support a particular theory.

I have been led to make this observation in consequence of having observed in many of the answers to the queries which you have proposed in the respect of burns, the frequent occurrence of the words "cannot say," and "I have no experience," terms which, if more frequently in use amongst medical writers, would wonderfully abridge the labour one now has to take in order to get at the marrow contained in the bulky carcasses of our numerous medical periodicals.

1. In Lancashire many modes of dressing are in use, of which cotton alone, flour alone, and cotton over a dressing of lime-water, oil, and spirits of turpentine, are those which I have myself used. In slight cases, where the destruction of the tissues is not deep, I *think* the cotton does as well as anything, or, perhaps flour, of which I have used little since I have become satisfied of the great advantages of cotton. In severer cases, and where there will necessarily be a good deal of sloughing and suppuration, I prefer dressing the parts first with the lime-water, oil, and turpentine, spread thinly over the burnt surface with a feather, and then applying the cotton (carded) equally over the whole. This double application appears to sooth the pain, and will remain on for two, three, or more days, before requiring change. It is a very common practice, and one in favour with the colliers themselves, to dress the parts with a cerate composed of soap, turpentine, and resin, with some oil spread on lint, and bandaged over. But even if equally unobjectionable with the liniment, this mode of applying what is nearly the same thing, gives rise to more uneasiness from motion, &c., and to more pain on its removal. As regards the latter part of the question, which contains the gist of the "stimulant" question, I am inclined to believe, from my own experience, that external stimulants are indicated almost solely in those severe cases in which internal stimulants are alone applicable, and for pretty much the same reasons,—viz., to rouse the system generally and locally from collapse.

2. I have no experience of cold applications, except in burns and scalds of very small extent.

3. Of the comparative value of cotton and flour I cannot decide—probably nearly equal ; but as far as I have seen, the cotton dressing is the more *manageable* of the two.

4. Except in very extensive burns, in which sedatives and stimulants, in turn, are required at first, I have confined my internal remedies solely to meet the emergencies of the case, watching particularly the action of the mucous and serous membranes as exhalant surfaces. With reference to this question, however, I cannot agree with those who think that our main efforts ought to be directed to the providing a vicarious

outlet for the suspended secretion of the skin. We have many analogous cases,—as confluent small-pox, for example, in which a fatal issue does not seem to depend so much upon the suspension of the healthy action of the skin, as a secreting and exhaling organ, as on the state of shock and alarm set up in the nervous centres, consequent upon the irritation of the peripheral extremities of so vast a number of nervous fibrils. To sooth disquietude, to support the failing strength, to relieve congestion, will all, therefore, in turn, require our prudent efforts.

5. No positive experience.

6. Ditto.

7. Ditto.

8. Dependent entirely upon the constituent symptoms. I have seen cases of the most severe and extensive burns recover almost without a bad symptom, but these have occurred to robust and previously healthy colliers. My fatal cases, except those destroyed at once, have been those of children, by whom, in consequence of their clothes taking fire, a more prolonged application of heat has been suffered than is the case in colliery explosions. Long continued collapse, with coma, almost imperceptible pulse, and coldness of the body, I have found invariably fatal.

9. Not sufficient experience.

10. The public ought to do nothing by way of treatment, in my opinion, but to envelope the burnt parts in cotton or flour, and to give a little brandy and water in extreme cases.

11. Answered in previous questions.

12. No precise recollection of any.

[Further communications may be forwarded to the Editor; or to Mr. Crompton, 71, Grosvenor Street, Manchester.]

MEDICAL LEGISLATION.

Proposed Clauses of a New Bill.

The following propositions as the heads of a measure of Medical Legislation, are the result of the conferences which have recently taken place between the Corporate Bodies, and the National Institute of Medicine, Surgery, and Midwifery.

"I. That a charter of incorporation should be granted to the surgeon-apothecaries of this country, under the title of 'The Royal College of General Practitioners of England.'

"II. That a council should be established to superintend the registration of all medical and surgical practitioners, and for the general control of medical education and practice.

"That the council should consist of one of her Majesty's Principal Secretaries of State, in right of his office, (who should also be president of the said council, with power to appoint a vice-president,) and that the other members of the council (of whom not less than two-thirds should be registered members of the medical profession,) should be such persons, not more than twelve, whom her Majesty, with the advice of her Privy Council, should deem fit to be members of the said council.

"That the council should be empowered, with the approval of the Secretary of State, to appoint a principal secretary, and local secretaries for Scotland and Ireland, and clerks, messengers, &c.; and that the members of the council, the secretaries, clerks, &c., should receive such salaries as the Lords of the Treasury should think proper to allow.

"III. That a register should be made and published by the said council, as soon as conveniently may be, of all persons entitled, as after explained, to be registered as physicians, surgeons, or general practitioners, and who shall apply to be so registered within one year if residing in any part of the United Kingdom, or within two years if resident abroad, for which a fee of ten shillings shall be paid by each person so registered; and that to the register should afterwards be regularly added the names of all persons who shall receive letters testimonial, as after explained, of their fitness to practise as physicians, surgeons, or general practitioners, and that for such registration should be paid the sum of five pounds in the case of a physician or surgeon, and of two pounds in the case of a general practitioner. All such fees should be applied towards defraying the expenses of this act.

"The register to be formed on the plan of a specimen submitted to the committee of the House of Commons in 1847 by the registrar of the College of Physicians.

"And all persons desirous of being continued on the register should be required to send their names and residences to the council annually, but without the payment of additional fees.

"The register is to be received as evidence in courts of law.

"IV. That those persons should be entitled to be registered as general practitioners who shall be enrolled as members of the Royal College of General Practitioners within one year from its first incorporation, according to the provisions of a charter which has been prepared for that college; and that those persons shall afterwards be entitled to be so registered who, having attained the age of twenty-two years, shall have received letters testimonial of their fitness to practise as general practitioners, from the examining board of the Royal College of General Practitioners, and who shall also have been examined and admitted as members of the Royal College of Surgeons.

"That those persons should be entitled to be registered as surgeons who shall have been examined and admitted as fellows or members by the Royal College of Surgeons. But, after the passing of the act, those who shall be admitted as members shall be also examined and admitted by the Royal College of General Practitioners, and registered as general practitioners.

"That those persons should be entitled to be registered as physicians who shall have been admitted as members of the Royal College of Physicians, according to the provisions of a new charter which has been prepared for the College of Physicians, and has also been submitted to the Government, which charter it is expedient should be granted to the College of Physicians.

"That the cases of persons who have been engaged in practice prior to the passing of the act, without being members of any corporate body in the profession,

should be referred to the college of the department in which they have practised respectively, for special investigation of their claims to be admitted to register.

"V. That the members of each class of the profession, registered in each of the three kingdoms respectively, should be entitled to be registered and to practise reciprocally in either of the three kingdoms as physicians, surgeons, or general practitioners, as the case may be, provided the education and examinations of each class respectively be assimilated and regulated by a certain standard common to each class; and provided that, previous to registration, they be enrolled in the college appropriated to their class, in the country in which they practise.

"VI. That the council shall be empowered to allow or disallow any new by-law which shall be made by either of the colleges.

"Also, cause a register to be made of medical and surgical students, and to make such dispensing regulations as shall seem fit in favour of those students who shall have commenced their professional studies before the passing of the act.

"Also to call for returns respecting examinations, and fees for letters testimonial and admission into the respective colleges, and to take such other measures as may be necessary in order to assimilate, as nearly as possible, the education, examinations, and fees for each class of the profession, respectively, in each of the three kingdoms. And that the council should be empowered, in any case in which it should appear to be necessary, in order to secure efficiency and uniformity of examinations, to depute one or more of its members to be present at the examinations of any of the colleges, provided the members of the council so deputed be medical practitioners, and of the same class in the profession as the college to be visited; and if, upon the report of such visitor, or otherwise, the council should be of opinion that its regulations are not complied with by any examining body, that it should be lawful for the council to refuse to register, upon the testimonials of the body so in default, until the same be amended to the satisfaction of the council.

"That the council should be empowered to strike from the register the names of any persons who shall be proved to have obtained the registry of their names by any fraud or false certificate, or who shall have been convicted of felony, or of having wilfully and knowingly given any false certificate in any case in which the certificate of a medical practitioner is required by law; also, the names of any persons who shall have been expelled from either of the colleges, according to the terms of their respective charters, provided such expulsion shall have been approved and allowed by the council, as before required, respecting by-laws.

"VII. That no one who is not registered should be judged capable of performing any act which is required by law to be done by a medical practitioner; nor should any but a registered person be appointed to any office which is deemed by the council to be a public medical or surgical office; nor should any but registered general practitioners be entitled to demand or recover fees for medical and surgical advice and attendance, or for medicines prescribed or administered.

"VIII. That penalties should be imposed by summary process on all unregistered persons practising medicine or surgery.

"Also, on all unregistered persons falsely pretending to be registered.

"Also, on all persons assuming any professional name or designation to which they are not by law entitled, or which implies that they belong to a class in the register in which they are not registered, or that they are members of a college in which they are not enrolled.

"In thus laying down the principles on which a bill should be framed for regulating the whole medical profession, the committee has entered into particulars only as regards the profession in England; but under the fifth head, respecting reciprocity of practice in the three kingdoms, it has assigned the conditions which are clearly indispensable for the attainment of that desirable object.

"The committee is aware that some variations from the plan which is here drawn out for England, may be rendered advisable or necessary, by local circumstances and the rights of existing institutions, in Scotland and Ireland.

"And the committee is contented that such variations should be made, provided the principle be not contravened, that equality of education and qualifications in each class respectively of the profession in the three kingdoms should be first obtained, in order that the right of reciprocal practice may be justly allowed."

SOUTH-EASTERN BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

POOR-LAW MEDICL RELIEF: THE CROYDON INQUEST.

At a special meeting of the South-Eastern Branch of the Provincial Medical and Surgical Association, held at Reigate, on Wednesday, the 1st of March, for the purpose of taking into consideration the recent case of the Croydon inquest, the conduct of the Board of Guardians, and the case of the medical officer in relation thereto, Edward Wallace, Esq., of Carshalton, President of the Branch, in the chair, the meeting having considered the subject of the late inquest at Croydon, as reported in *The Times* of the 12th of January, and the resolutions of the Board of Guardians of the Croydon Union, contained in *The Times* of the 19th of January.

Resolved—

"1. That it appears to this meeting that Dr. Berncastle having been called to Mrs. Howard, as the Union Medical Officer, attended immediately, and continued his attendance for several hours, until finding that the Board of Guardians had declined to

recognize her as a pauper patient, and had positively refused a medical order, exercising his undoubted right to accept or decline her as a private patient, he discontinued his attendance.

"2. That this meeting expresses no opinion as to the propriety of Dr. Berncastle's having left the patient, because, under the circumstances of the case, his continued attendance would have been an act of private charity, entirely within the control of his own conscientious feeling, and in no way compulsory upon him.

"3. That, however, it is the deliberate opinion of this meeting, that the verdict of the Jury, in so far as it attributes to Dr. Berncastle 'the greatest inhumanity,' is characterized by the greatest injustice, and is entirely contrary to the evidence.

"4. That the Board of Guardians having adjudicated upon the case, having repudiated it as a case requiring the attendance of their medical officer, and having refused the medical order, thereby assumed to themselves the responsibility of the poor woman being left without attendance, and released their medical officer from further responsibility to them in the matter.

"5. That the Board of Guardians having pleaded a want of knowledge of the actual circumstances of the case, this meeting cannot consider such plea to be valid, inasmuch as having received a personal application from the daughter of the patient, and the relieving officer being present who had investigated the case, they had before them all the means of information.

"6. That this meeting can consider the resolutions of the Board of Guardians only as an attempt to avert public animadversion from themselves, by the sacrifice of the reputation of their medical officers—a course of proceeding which must excite the indignant reprobation of every honest mind.

"7. That the censure passed by the Board of Guardians on Mr. Tipple, for giving his opinion on oath at the inquest, is an unworthy act of intimidation, which this meeting hopes will not prevent that gentleman or any other medical officer from giving his conscientious opinion on a fitting occasion.

"8. That this meeting is cognizant of the zeal and assiduity with which Mr. Bottomley has for upwards of thirty years attended the sick-poor of Croydon, and deeply regrets that his compliance with the instructions of the Board of Guardians should have brought upon him censure from that body, who were bound either to have given him their support, or to have taken their full share of any blame which might be incurred.

"9. That the resolutions of this meeting be inserted in *The Times*, *The Daily News*, the weekly medical journals, and in the local papers.

"10. That the best thanks of this meeting be presented to Mr. Wallace for his able and judicious conduct in the chair.

THOMAS MARTIN, Secretary.

Reigate, March 1, 1848.

General Retrospect.

ANATOMY.

DEFICIENCY OF THE STYLO-HYOIDEUS MUSCLE.

The following are the notes of a dissection, by Moses Gunn, M.D., of Ann Arbor, Michigan, exhibiting an entire deficiency of the stylo-hyoideus. Subject—a negress, apparently about sixteen years of age, and well formed. The integument and external layer of superficial fascia were dissected up, and exposed a tolerably developed myoid. Removing this, and the sterno-cleido-mastoid with usual care, Dr. Gunn commenced the dissection of the supra-hyoid region. The anterior belly of the digastric was dissected out to the point where its tendon passes into the loop of the fascia which connects it to the hyoid bone. In dissecting out its posterior belly, it was observed to be beautifully developed, though not much exceeding its usual size, and not to pierce muscular fibres, as it usually does those of the stylo-hyoid. The dissection was continued by laying open the loop of fascia which invests its tendon, and turning back the muscle to its origin. This exposed, not the fibres of the stylo-hyoid, but a layer of fascia, removing which, brought to view the stylo-glossus and stylo-pharyngeus in their natural position, and ordinarily developed. Adjacent parts were perfectly normal, but not the least trace of the stylo-hyoid could be found. The dissection was repeated upon the opposite side, with additional care, and with the same result.—*New York Journal of Medicine*, September, 1847.

ABNORMAL CONDITION OF THE URINARY APPARATUS.

Dr. Hargrave exhibited the parts taken from a subject which had been obtained for practising lithotomy, and which displayed a curious malformation of the kidneys, ureters, and bladder. On incising the integuments of the perineum, he cut into a sinus or pouch, from which urine issued. This led him to examine the abdomen. The left kidney was found enlarged, and its ureter immensely dilated and sacculated. On following the dissection into the pelvis no bladder could be discovered. The vesiculæ seminales were in their usual situation.

The portion of the ureter, which from its sacculated dilatation represented the bladder, was lined with muscular fibre. The right kidney was scrofulous, and its ureter impervious.—*Dublin Medical Press*, Jan. 28, 1848

PRACTICAL MEDICINE.

TREATMENT OF INTESTINAL HÆMORRHAGE OCCURRING DURING TYPHOID FEVER.

M. Martin Solon employs the following treatment in this dangerous complication:—He gives as a drink iced rue water, to which is added a decoction of extract of rhatany. Night and morning he orders an enema of a decoction of the same plant. A bladder of ice is eventually applied to the cæcal region, and at the same time blisters are applied to the extremities. He relates several cases in which this treatment was completely successful.—*Bulletin de Thérapeutique*, Oct., 1847.

NAPHTHA IN PHTHISIS.

[Our readers have probably not forgotten the introduction of this so-called *remedy* for consumption three or four years ago, and doubtless were not slow to discover the charlatanism which presided over the announcement. Should there be any believers in its virtues still left among the members of the Provincial Association the following testimony will, we feel assured, be thankfully received.]

At a recent meeting of the Medical Society of London, Dr. Theophilus Thompson stated that he had endeavoured to ascertain as far as lay in his power, the effects of this remedy, at the Consumptive Hospital. With this view, having taken proper precautions to get the agent pure, and to give it as described by its admirers, he administered it in several cases. The conclusions arrived at were these:—In the third stage of phthisis it did positive mischief. In a few cases, where the bronchial tubes were affected and there was much expectoration, it seemed to arrest the secretion to some extent, before the night perspiration, and sometimes to relieve the cough. In all other stages of consumption, and under all other circumstances, naphtha did positive harm. It had no effect whatever on the tubercular disease.

Dr. Goldiug Bird had also employed it with all due caution, but had never found it of the least service. In chronic bronchitis it acted as the other hydro-carbonates, but with no greater effect. To say it cured or arrested consumption was a mere delusion.

Similar testimony was borne by Mr. Hird and by Dr. Wilshire.

Mr. Fisher related some cases in which benefit was produced, but he owned that their diagnosis was uncertain.

TURPENTINE IN DIABETES.

A correspondent of the *Lancet* writes to the following effect:—In the absence of any medicine having any immediate or certain influence over diabetes, any remedy which can mitigate and temporarily arrest, if not cure, this malady, must demand attention. A patient of mine, aged 44, of a scrofulous diathesis, has been suffering from diabetes for ten months, during which period the minimum quantity of water passed daily was nearly two gallons. About six weeks since, alarming hæmoptysis appeared, (phthisis having supervened,) to relieve which I administered spirit of turpentine. With the first dose the quantity of water diminished greatly, and after she had taken two or three doses of turpentine, the urine was passed in its normal quantity, though not in its normal condition, as I could still obtain sugar by evaporation. I regarded this improvement in the diabetes as a mere coincidence, but on withdrawing the turpentine the water again increased, and that dreadful thirst, which had been absent, returned.

As the urine passed continued in very large quantity, I again had recourse to turpentine in the form of Chio turpentine. Instantly, as by magic, the quantity of urine decreased, has remained so, and I well know that were I to omit the turpentine for one day, two gallons and a half of water would be the result.

PHOSPHATIC DEPOSITS IN THE URINE OF CHILDREN.

Mr. Grantham states that he has recently attended three children in one family, whose parents had previously lost three other children, two from serous effusion in the brain, and one from atrophy. The general appearance of the children presented a lax condition of the muscular system, with fair complexion, unequal diffusion of heat, dark eyes, indisposition to exertion, and constipation. The patients complained of weary and painful sensations in the parts supplied by the lumbar plexus. On examination of the urine it was found of a pale straw colour, specific gravity 1020, and without deposit after standing. Further analysis shewed an undue proportion of the mixed phosphates in the urina sanguinis, but not in the urina potus. The treatment consisted of abstinence from sugar, fruit, &c.; the tepid bath; flannel clothing; and the exhibition of nitro-muriatic acid, followed by steel.—*Medical Gazette*, Dec. 17, 1847.

SURGERY.

CASE OF SPINA-BIFIDA IN WHICH THE TUMOUR WAS SUCCESSFULLY REMOVED.

Mr. Page, of Carlisle, has recently published the particulars of a case of spina-bifida, in which he successfully removed from the lumbar region of a female child, two years of age, a tumour which measured seven inches in its greatest circumference, and five inches at its base. The child was healthy and intelligent, and otherwise well-formed; had no paralysis, and gave no evidence of pain when pressure was made on the tumour, the fluid contents of which passed readily into the spinal canal.

The tumour had gradually increased from the time of birth, and from the unhealthy character of the integuments covering it, was plainly progressing towards a fatal termination; but the general circumstances of the case seemed to warrant an attempt at cure if such attempt be ever advisable.

Believing that the danger of interference is proportionate to the size of the communication between the interior of the cyst and the vertebral canal, Mr. Page endeavoured to diminish that communication by placing an elastic ring of India-rubber around the base, which was retained there until ulceration was produced. By this means the base of the tumour was lessened considerably, as was the case when the same means were repeated two months later. At the end of a few months Mr. Page removed the tumour in the following manner:—He dissected two semi-lunar flaps of the skin from its surface, applied a strong ligature close to the base, and removed all that was external to the ligature. On the sixth day the ligature with its enclosed portion of tumour came away, leaving a wound somewhat larger than a shilling, in the middle of which the membranes of the cord were distinctly seen. The child was kept lying on its abdomen with a flannel bandage constantly applied round the boby, and five weeks after the operation the wound was perfectly healed. Since that time the child has suffered no

inconvenience, the cicatrix has much contracted, and the vacancy in the posterior walls of the vertebral canal has perceptibly diminished.

The examination of the tumour demonstrated that it was a cyst of sufficient size to contain a small walnut, its walls being formed by an expansion of the arachnoid and dura-mater, invested by the common integuments. No nerves were found connected with the interior of the cyst.

Mr. Page remarks that "the means adopted in the foregoing example of spina-bifida are only applicable to those cases in which the base of the tumour is more or less pediculated, and of these there are but few in which such interference could be employed with any prospect of success, the cord, or its nerves, being in a great majority of instances connected with the interior of the cyst. But, inasmuch as the tumour almost uniformly enlarges until ulceration of its walls takes place, speedily followed by death, it is important to distinguish, if possible, those which have no such connections, and in which the tumour may be removed with no other danger than that resulting from the exposure of, and injury to, the membranes of the cord—a danger in itself sufficiently alarming, and to incur which could only be rendered justifiable by the fatal nature of the affection it is intended to remedy. The absence of any morbid sensibility when the tumour was moved upon itself, or when pressure was exerted on any part of it, together with the perfect formation of the lower limbs, and the entire control over them, the bladder and rectum, were, in the present instance, considered sufficient evidence of there being no nervous filaments connected with the interior of the cyst, and probably the same diagnostic signs would furnish equally correct information in most, if not in all cases." And he adds "that the instances of spina-bifida in which the skin and membranes have been sufficiently strong to support the distension, and in which life has not been curtailed by the presence of the tumour, although very limited in number, are sufficiently numerous to warrant no active interference, where the slow increase of the tumour and healthy appearance of the skin afford any probability of so favourable a result."—*Monthly Journal of Medical Science.*

FREQUENCY OF HERNIA.

By Arnaud it has been calculated that one-eighth of mankind are the subjects of hernia. Mr. Turnbull, surgeon of the London Truss Society, states, that "after most diligent and general inquiries throughout the kingdom, he is induced to take them, male and female, and of all ages, upon an average of 1 to 15." This estimate was sanctioned by Monro, supported by the authority of Gimbernat, and was, for many years, generally adopted by European surgeons. It is undoubtedly too high, but other surgeons have erred in the opposite extreme. From a return made by Dr. Vesturme, Inspector-General of the German-Legion, it appears, that of 40,460 recruits examined, 365 were rejected on account of their being affected with hernia,—nearly 1 in 111, or a little less than 1 *per cent.*; and of 12,835 recruits inspected in Dublin, 116 were rejected on account of the infirmity, or 1 in 110. It has been supposed that these returns afford a tolerably correct view of the general frequency of hernia, at least in the male population of European states; but the estimate is obviously too low, for many persons afflicted with hernia, and knowing it to be a ground of disqualification for military service, would on this account be prevented from enlisting. A nearer approach to the truth, as far as regards the male population of France, of 20 to 21 years of age, may be obtained from the records of the French conscription. Thus, according to M. Malgaigne, of 10,247 persons examined from 1816 to 1823, in the department of the Seine, 314 were hernial, or 1 in 32; and of 754,875 examined throughout the whole of France, from 1831 to 1837, 24,221 were exempted on account of hernia, or nearly 1 in 32. Assuming, then, that there is 1 hernial subject in 32 males in France of 20 to 21 years of age, and calculating the relative proportions of hernial subjects at different ages, and in each of the sexes, M. Malgaigne arrives at the following estimate—namely, that there is 1 hernial subject in 13 of the whole male population of France; 1 in 50 of the whole female population; and 1 in 21½ of the entire population. From various observations M. Malgaigne infers, that the relative proportions of hernia in men and women is as 4 to 1. Other statements show a great preponderance of hernia in the male sex; but it may be justly supposed that it is greater than really exists, since women, from motives of delicacy, as well as from their being less engaged in such laborious occupations as compel the hernial subject to seek relief, are less likely than men to be the applicants at a public institution.—*Teale's Practical Treatise on Abdominal Hernia.*

CRURAL NEURALGIA CAUSED BY INGUINAL HERNIA.

It is well known that in certain cases of crural hernia, a sensation of weight and dragging, together with true neuralgic pains, is felt along the course of the crural and saphena nerves; but these symptoms are not commonly produced by inguinal hernia. The following instances are on this account worthy of record:—

1. A baker, aged 45, was the subject of inguinal hernia of the left side. Soon after the appearance of the tumour, he began to have pain in the course of the cord, and in the anterior and inner part of the thigh. These pains radiated down the thigh even as far as the dorsum of the foot. They were without interruption during the day, and were greatly exasperated by coughing; at night or in the recumbent posture they were alleviated. M. Melchiori, who relates the case, having recognized the hernia, caused the patient to wear a truss, after which the pains soon subsided, but re-appeared if the patient by any accident forgot his truss, and the intestine in consequence became again engaged in the inguinal canal.

A second case in most respects entirely similar is also reported.—*Gazetta Medica di Milano.*

TUMOUR OF THE NECK SIMULATING CAROTID ANEURISM.

The following case in which Professor Syme, with a rare honesty, narrates an instance of his own error, is strikingly worthy of perusal.

A young man called upon Professor Syme for his opinion on a tumour, occupying the upper triangular space in the right side of the neck. It was oval, circumscribed, and obviously contained fluid. There was a distinct expansive pulsation not limited to any portion of the tumour, but equally felt at every point. The patient stated that it increased in size upon exertion, and that the pulsation became stronger. There was no distinct aneurismal bruit, but a loud strong pulsation was audible. Under these circumstances no doubt was entertained of its aneurismal character, and the carotid was tied by Professor Syme. The tumour immediately sensibly diminished in size; the patient went on favourably for some days, but eventually died of secondary hæmorrhage.

On examination after death, no aneurism was present; the tumour consisted of a cyst, containing matter of a gruelly consistence, and was ultimately connected with the carotid sheath.

[In commenting upon this case, Professor Alison said that it clearly proved that even external aneurism could not always be diagnosed with certainty; internal aneurisms he had long been convinced could not in many cases be detected during life. This admission on the part of one of the best pathologists of the day affords an instructive contrast to what has recently been advanced in a weekly contemporary on the subject of stethoscopic accomplishments.]

SUBCUTANEOUS INCISION OF CYSTIC TUMOURS.

Dr. A. C. Neumann, of Grandenz, believes this method of operating to be unjustly neglected; the trifling pain to the patient,—speedy recovery,—absence of cicatrix,—its practicability on the scalp, without removing the hair, and also in the immediate neighbourhood of vital organs, large blood-vessels, or nerves, form its advantages over extirpation. He operates by introducing a long narrow tenotomy knife, with a sickle-shaped point, under the skin, about half an inch from the cyst, passing it through the subcutaneous cellular tissue to the walls of the tumour, which are then penetrated, and its lining membrane incised in as many places as possible. As much of the contents as possible are now removed by strong pressure; sometimes the whole is evacuated, at others only a portion. The cyst sometimes inflames, and pus escapes by the wound, causing the cure to be more tedious; in general a hard portion only continues to be felt, for a longer or shorter time, under the skin. A simple linen compress, retained by strips of plaster, was all the dressing employed. The result has always been favourable. In no case has any return of the tumour been observed, which the author believes to be the result of the careful incision of the lining membrane. —*Casper's Wochenschrift*, Feb., 1847.

OBSTETRIC MEDICINE.

RUPTURE OF THE UTERUS FATAL ON THE FOURTH DAY AFTER DELIVERY.

The following case came under the observation of Dr. Smalwood, St. Martin, Canada:—The patient, aged 28, with narrow pelvis, in labour of her fourth child, had been in labour twenty-four hours, and turning had been unsuccessfully attempted before Dr. Smalwood was sent for. When he arrived he found her in a state of collapse, but without pain. The appearance of the abdomen led him to suspect the cause of these symptoms, and on examination he could distinctly feel the breech of the child in the peritoneal cavity. Examining per vaginam the head was found to present. Opium and stimulants were given immediately, and delivery was effected by lessening the head, and drawing it down by the blunt hook. The body followed readily, and as the placenta was removed, the uterus contracted well, and without hæmorrhage. The rent in the uterus had been previously felt by passing the hand into the uterine cavity. The woman rallied considerably for three days after delivery, and the lochia and milk were secreted naturally; but she sank suddenly on the fourth day. No examination was allowed.—*British American Journal*, Jan. 1848.

RUPTURE OF THE UTERUS OCCURRING DURING LABOUR: RECOVERY.

Cases of recovery after rupture of the womb are such an occurrence that we are desirous of recording the leading features of this one, the subject of which had to contend alike with her formidable accident and the neglect of her attendant. A woman, aged 37, of muscular make, and very choleric temper, had been in labour for six or eight hours, on the 1st of February, when at about four p.m., on getting on to the bed, she was seized with a tremendous pain, contemporaneously with which the waters were discharged, and a loud cracking sound was heard. She complained of terrible suffering at the umbilical region, and grasped this with both her hands. Labour-pains ceased, and she became ghastly and cold, so that her friends believed her in the act of dying, and had the religious sacrament administered. After a long period, however, they determined to call in advice, and about six hours after the accident the author, Dr. Prassart, saw her. He found her suffering from the extremest prostration and intense tenderness of the belly, through the parietes of which the parts of the child were plainly felt. He easily delivered her of a dead child by means of the forceps, and a large discharge of blood followed. He endeavoured to ascertain the size and position of the aperture, but could only discover that his hand passed at once into the cavity of the abdomen, whence he removed the placenta, and that large coils of intestines passed into the uterus, the great pains induced forcing him to desist. The woman, after this, seemed almost lifeless, and Dr. Prassart informed her friends that she could not live the night. With true Germanic phlegm, he seems to have taken no pains to ascertain whether his prediction was verified, and in *four days* after was much surprised at being again called to visit the patient. He now found severe inflammatory action of the womb and abdomen set up, accompanied by great prostration of strength. We need not follow the case through its remaining details, presenting as it does but another example of the occasional wonderful power which nature employs in coping with the direst extremities of disease. The author, from his infrequent visits, (alternate days,) and the nugatory character of his treatment, may be

considered as having delivered it over into her hands, the result being, that in four weeks the woman was enabled to leave her bed. She continued for some time after her recovery to be tormented with occasional severe pains, but in the course of the following year natural menstruation was re-established.—*Casper's Wochenschrift*, No. 41, 1847.

POOR-LAW MEDICAL RELIEF.

CONFERENCE WITH THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

On Friday, February 18th, a deputation from the Committee of Poor-Law Medical Officers was favoured with an interview with the Council of the Royal College of Surgeons The deputation, consisting of Dr. Hodgkin, Mr. Vallance, Mr. Mitchell, Dr. Barnett, Mr. Lobb, Mr. Lord, Mr. Bottomley, and Mr. Peter Martin, were received by the President, Mr. Travers, and by Mr. Green and Mr. Stanley, the Vice-Presidents, of the College.

The deputation stated in detail the evils attending the present system of medical relief, both as regards the medical profession and the poor, and submitted to the College the heads of a plan they had agreed upon, as containing the principles of a better system. They reminded the College that the only improvement which had hitherto been made in the system since the introduction of the new Poor-Law had been in a great measure owing to the exertions of their former President, Mr. Guthrie, and explained that by the general reduction of salaries consequent on the medical order, Mr. Guthrie's plan had paatially failed in giving the relief intended. The deputation particularly dwelt on the necessity of placing Poor-Law medical relief under competent professional control.

The President and Vice-Presidents of the College assured the deputation of the interest felt by them in the matter, and of their approval of the principles set forth by the deputation. Without committing themselves to the details of the plan, they gave an assurance that it should have the full consideration of the Council, and intimated that the Council sympathised fully with the objects contemplated by the Committee of Medical Officers, and would be ready to give them an active support.

DR. BERNCASTLE AND THE GUARDIANS OF THE POOR OF THE PARISH OF CROYDON.

At a meeting of the surgeons to the parish of Birmingham, it was unanimously resolved,—

"That this meeting considers that the conduct of Dr. Berncastle, in his attendance on the woman Howard, at Croydon, in January last, was highly commendable and humane."

"That the Board of Guardians, having refused to allow her to be a parochial patient (most unjustly we believe,) had no authority to interfere subsequently in the case under any circumstances."

"That such refusal having caused the cessation of Dr. Berncastle's attendance upon the case, his responsibility immediately ceased, and whatever consequences might be attributed to such non-attendance, the blame must rest with the Guardians, and not with him; hence the charge of neglect against that gentleman and his consequent dismissal were entirely the result of his obedience to their own instructions."

"That after a careful consideration of the evidence adduced at the inquest, there is not the slightest foundation for any charge of neglect against Dr. Berncastle, or for the unmanly and oppressive conduct of the Guardians towards him, or for the extraordinary and illegal verdict of the Jury."

"That the ingratitude evinced towards that gentleman for his gratuitous attendance on a poor woman in a case of emergency, is calculated to have considerable influence in preventing the gratuitous services of the medical profession towards the poor generally."

"That the above resolutions be advertised in the *Times* newspaper, and copies sent to Dr. Berncastle, to the *Lancet*, *Medical Times*, *Medical Gazette*, and *Provincial Medical and Surgical Journal*."

Thomas Green, Robert Macpherson, John Simons, Frederick Field, Lewis Hill, John Onions, Samuel Badger, William Hoare, W. M. Richards, Josiah Clarkson, William Hinds, J. G. Sproston, George Richards, *Medical Officers*.

THOMAS CLARKE RODEN, Hon. Sec.

Birmingham, February 21, 1848.

TESTIMONIAL TO DR. BERNCASTLE.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I have this day addressed a note to the Editor of the *Lancet*, calling on the medical profession generally, to enter into a subscription for the purpose of presenting a purse to Dr. Berncastle, in testimony of their sympathy in his cause.

As a Member of the Provincial Medical and Surgical Association,—although I am sorry to say, a very useless one—a recipient of its benefits, conferring nothing in return,—I doubt not, my appeal will be heard and responded to by my Associates.

If gentlemen in different parts of the country would bestir themselvs, a sum worthy of the acceptance of Dr. Berncastle, could in a very short time, be collected. I beg to inform you that I will readily receive subscriptions from gentlemen in my neighbourhood, and put down £5 in the names of two friends and myself.

Trusting to receive your able advocacy in the cause,

I am, Sir, yours obedient,

C. WILSON STEEL.

Lewisham, February 19, 1848.

SUPPLY OF VACCINE MATTER: OPIUM IN STRANGULATED HERNIA.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

It may perhaps be within your recollection, that in November, 1845 and 1846, I offered, through the medium of your Journal, to supply vaccine virus to

such members of the Association as might require it. My offer was so far well-timed, that I had upwards of two hundred applications. A large portion of my correspondents complained of the inefficiency of the virus supplied by the Institution in London; and one gentleman gave it as his opinion, that nothing but mucilage had been occasionally sent him. I have recently received the following letter; its suggestions are so good, that I will leave it to speak for itself:—

"Sir,—Rembering your kindness to me, on a former occasion, I have inclosed you a supply of fresh vaccine virus, and shall have great pleasure, whenever it may be in my power, to repeat it. It has often occurred to me how much benefit, and what a convenience it would be, not to medical men only, but to their patients also, if the various members of the Provincial Medical and Surgical Association would distribute, per post, amongst those of their acquaintance, the surplus virus which they frequently have by them, as by so doing, they would in a great measure remove the difficulty which so often exists, in procuring a supply of so valuable an article.

"I am, &c. &c."

The unexpected supply referred to proved a most seasonable one, as I was much in want of it, and knew not whence to obtain it.

I will here mention an interesting case of strangulated scrotal hernia, of recent date, in which the good effects of opium were most manifest. The subject was a painter, a very fine well-made man, who has long been subject to scrotal hernia of the right side, for which he usually wears a truss. The bowel occasionaliy comes down, but he has hitherto always succeeded in putting it up again. In reaching above his head, while at work, the hernia suddenly protruded, and all his efforts at reduction were fruitless. I saw him shortly afterwards, and all the usual means were tried in vain. I endeavoured to produce syncope by venesection, but so unusually large a quantity of blood was abstracted without success, that it was deemed prudent to desist. I then gave him one grain of solid opium every hour. After four doses the bowel was easily returned, and he had not since a bad symptom.

Many years since (upwards, perhaps, of twenty,) two cases occurred to me, in which I bled *ad syncopen*, and used the warm bath, &c., without success. In both these I then gave a good dose of laudanum, and left them, in the full expectation of being under the necessity of operating; but on quickly repeating my visits, I was rejoiced to find that in both cases the hernia had disappeared. I was then much more disposed to attribute the good effects to the venesction and warm bath, than to the opium.

I am, Sir,
Very truly yours,
T. P. FERNIE.

Medical Intelligence.

APPOINTMENTS.

Thomas Barrett, Esq., has been unanimously elected one of the Medical Officers of the Bath Eye and Ear Infirmary, in the room of S. Edwards, M.D., who has left Bath.

M. Bonillaud has been nominated Dean of the Faculty of Medicine, Paris, in the room of M. Orfila, who has been superseded by an order of the new Provisional Government.

M. Berard has been re-appointed Dean of the Faculty of Medicine, Montpellier, in the room of M. Ribes.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, Feb. 17, 1848:—Samuel Franceys Gosling, Congleton; John Orred, Liverpool; Charles Devonport Rook Symons, Devonport; Thos. Hore Graham, Stoke in Devonport.

Gentlemen admitted Thursday, February 24:—Charles Jennings; John Farmer, Hereford.

OBITUARY.

Died, February 6th, aged 88, William Daw, M.D., Chicklade House, Hindon, Wilts.

February 12th, at Bury St. Edmund's, aged, 83, Thomas Smith, M.D., lately Physician to the Suffolk General Hospital, and formerly to the Nottingham Infirmary.

February 18th, of fever, Robert Twiss, M.D., Medical Attendant of Bird Hill Dispensary, County of Tipperary.

February 29th, at Hertford, aged 67, Geo. Dickens, Esq., M.R.C.S., Consulting Surgeon to the General Infirmary.

Lately, Thomas Sumner, Esq., Surg on, n le Willows, Lancashire.

MEMOIR ON TURNING, AS AN ALTERNATIVE FOR CRANIOTOMY AND THE LONG FORCEPS, IN DEFORMITY OF THE BRIM OF THE PELVIS, &c. &c.*

By J. Y. Simpson, M.D.,
Professor of Midwifery in the University of Edinburgh.

Sect. VI.—The Depression and Indentation during Labour of the sides of the Infantile Cranium, is compatible with the life of the Child.

Among the advantages of turning as compared with embryulcio, I have stated that "it gives the child a chance of life," and that the "neck of the child, if it be living or only recently dead, is so strong as to allow us to exert such a degree of traction upon the obstructed head, that the sides of the cranium may become greatly compressed or even indented under it; and that without necessarily destroying the child."†

As a comment upon these statements, Dr. Radford observes, "It has been said that the neck of the child alive, or recently dead, is so strong as to allow such a degree of force to be used as to greatly compress the sides of the cranium; *but* (he adds,) *such a procedure is at variance with all scientific views, and incompatible with the safety of both mother and child.*"‡

The accuracy or inaccuracy of the two different, and indeed, opposite opinions, thus expressed upon the same point by Dr. Radford and myself, is one of those questions in pathology which no mere opinion or mere reasoning could ever settle. In order to decide it, we must have recourse to facts and experience alone. And it is of the highest moment in relation to the whole object of the present enquiry, that the evidence on the matter be as perfect and unequivocal as possible; for, in fact, the practice proposed is based in the main, on the fundamental idea that the required compression and indentation of the infantile skull is *not* incompatible—as craniotomy is—with the continuance of infantile life.

Now, the records of midwifery contain numerous accurately-observed cases in which the cranium of the child has become greatly compressed or flattened, or actually depressed and indented in one of its sides, while passing through a very contracted pelvis, and that too, without necessarily destroying the life of the infant. Velpeau, for instance, the only author whom Dr. Radford quotes, tells us in a part of his work, which has evidently escaped Dr. Radford's observation, that the depression or "indentation (*enfoncement*) of the parietal or frontal bone, with or without fracture, has been noticed several times at the Maternity Hospital of Paris." * * * And "If (he observes,) the fracture or depression of the bones is not accompanied with effusion, nature ordinarily suffices to restore things to their primary state, and charges herself with the burden of the cure. Otherwise death is the usual consequence of them, or at least they produce drowsiness (*assoupissement*) and a great tendency to convulsions."*

Chaussier, who tells us that he had reported some examples of these depressions and indentations of the infantile skull in 1807 and 1810, makes the following judicious observations upon their general pathology and effects. "Sometimes," he observes, "when the sacrovertebral angle projects too far forward, we find on the portion of bone which rested on this prominence an indentation or depression, (*enfoncement ou depression,*) at which we often remark several small linear fissures (*fêlures*) in the form of a star, proceeding from the centre of the depression, and limited to the internal surface of the bone; at other times the bone is fractured in all its thickness, and its fragments are more or less separated, or forced in upon the brain; most commonly the infant dies in the act of delivery, or a short time after its birth." * * * * "These lesions, however, which would," he adds "be always fatal for an adult, do not always terminate so badly in the new-born infant, for, at this age the brain has neither the consistence, nor the action or use which it ought to have subsequently; they even heal easily and spontaneously if the infant be vigorous, and the labour has not been too prolonged."†

Various practical authors have left incidental notices of such cases of depression observed in the skull of the

infant at birth, without the life of the child being compromised by the injury. Sometimes the injury has been the result of an excessive degree of compression by the forceps; but more usually it has been produced (as pointed out by Chaussier,) by the head of the infant being strongly crushed against the projecting promontory of the sacrum, and whether the infant passed as a cranial or footling presentation. Dr. Smellie, in his "Collection of lingering cases from a small, narrow, or distorted pelvis," prefaces his observations with this general remark, that "although these labours may seem to be of the same class, and require the same management with those that proceed from a large head, there is an essential difference; for though they are much the same with regard to the efforts of the woman, the operator in these has much less room when he is obliged to assist with his hand, and the child's head is disfigured and compressed into *large indentations*, occasioned by the jetting in of the upper part of the sacrum, and of the vertebræ of the loins."*

In the course of his valuable volumes Dr. Smellie in different parts casually details several instances bearing out this remark, and at the same time shewing that the injury is not necessarily fatal to the infant. I shall abridge some of these cases.

Case XVIII.—In a woman,† "sickly from her infancy and very much distorted," Dr. Smellie effected the delivery of a living child by a double application of the forceps. "The forceps when first fixed had impressed the forehead, though the mark disappeared in five or six days after birth; but they made a very considerable impression when they were fixed a second time along the ears." The pelvis was "distorted from the jetting forwards of the upper part of the sacrum," and this projection had produced an *indentation*, distinct from those produced by the forceps; "the head was of a lengthened form, and contorted to one side, and there was a *deep impression* above the ear."—"Had the child been large its life could not possibly have been saved."

Case XIX.‡—The descent of the infant's "head was retarded by a jetting-in at the middle of the sacrum," and the forceps were used. "The child's head was squeezed into a longitudinal form, flattened on the sides, with a *deep impression* on the cranium above the ears; and from an indentation on the os frontis by a blade of the forceps, which had been fixed on that and the occiput, I discovered the ears were not to the sides as I had imagined. These impressions (the author continues,) had very much galled and inflamed the parts, but in consequence of proper care they digested, and the child recovered, and as he grew up the marks diminished and disappeared."

Dr. Smellie describes a case of depression and injury of the infant's cranium at birth that is still more important than the preceding two in reference to the subject of the present inquiry, for in it the cranial indentation was produced in following the very practice which I am discussing,—viz., in turning the infant when the brim of the pelvis was narrow and contracted. The following are the principal particulars:—

Case XX.*—A patient had "a narrow and distorted pelvis," in consequence of "the three lowest vertebræ of the loins bending forwards." The patient was delivered four times. At her first and third labours the infants were obliged to be extracted by the crotchet. Dr. Smellie tells us that he "managed her second labour from the beginning in a slow and cautious manner; but (adds he,) although the child was small, I with the greatest difficulty saved it by the assistance of the forceps." At her fourth accouchement the shoulder presented. Dr. Smellie tried ineffectually to perform cephalic version, and then with some effort seized one of the legs of the infant and turned it, and extracted it as far as the neck, the head still remaining above the contracted part of the pelvis. After using considerable exertion in order to drag it through the deformed brim, Dr. Smellie states that he began to despair of the child's life, but adds, "as there was still a weak pulsation in the funis, I resolved to make another effort with all my strength, by which the head was moved a little lower; then forcing up my fingers to the forehead, I got a firm hold of it, and finished the delivery." The infant shewed some weak signs of life, and in about ten or fifteen minutes began to cry. "The infant (adds Dr. Smellie,) continuing to cry incessantly while the head was washing, I examined and perceived a large tumour above the right ear; I likewise found a *depression of the temporal bone* before the ear, and the frontal and parietal bones pushed outwards; these formed the swelling, and were the parts that stopped at the distorted bones of the vertebræ." The child was quieted by applying pressure on the tumour with a compress and bandage. Next day the swelling had disappeared. The mother recovered better than in any of her preceding labours.

Dr. Smellie relates another case† in which the head of the child was apparently injured in a similar manner in dragging it through "a distorted pelvis."

Case XXI.—The infant presented by the breech. After the body and extremities were born, "a good deal of force was used to deliver the head." Five minutes elapsed before the child breathed; at last it began to cry incessantly, "till one of the women observed a large swelling betwixt the left ear and temple." Pressure with the fingers first, and ultimately with a compress, quieted the child in the same manner as in the preceding case. "When I examined it (says Dr. Smellie,) next day, the swelling was gone, and it appeared to have been that part which stopped so long at the projection of the upper part of the sacrum before the head was delivered."

* Collection of Cases and Observations, Vol. iii., p. 230.
† Cases and Observations, Vol. iii., p. 95. Collect. 32, Case 11.

Dr. Denman has recorded one exceedingly interesting case, in which the head of the infant was much injured during the version and extraction of it through a deformed pelvis, and that, as in the preceding cases of Dr. Smellie, without compromising the infant's life. The case is altogether so pertinent to the subject of the present remarks, and affords so much important corroborative evidence, that I feel assured I shall be excused in giving the details in full, and in Dr. Denman's own words:—

Case XXII.—"Many years ago I attended a patient in two labours, in both of which there was a necessity of delivering with instruments, on account of the smallness and distortion of the *pelvis*, and neither of the children could be preserved. In her next pregnancy I made a proposal to bring on premature labour, to which she and her friends would not consent, and I was dismissed from my attendance. In the course of twelve or fourteen years she had five more children, not one of which was born living. In the forty-sixth year of her age she proved with child, and again applied to me. When her labour came on, the first stage was suffered to proceed without interruption, but when the membranes broke, I without delay passed my hand into the *uterus*, and easily brought down the feet and body of the child; but the head being stopped by the narrowness of the superior aperture of the *pelvis*, I was obliged to exert, and continue much force, before it could be extracted. The child was born with very little or no appearance of life, but by the strenuous use of the common means recommended for this purpose, it was recovered. On the left parietal bone there was a depression of considerable extent, and to my apprehension of full one inch in depth, occasioned by the projection of the *sacrum*, but the depressed part gradually rose. In the course of a few months the bone regained its natural form, and the child was for several years in good health, with its faculties perfect. The woman recovered without any untoward circumstance."

"But (adds Dr. Denman, in a cautious and contradictory note,) the success of such attempts to preserve the life of a child is very precarious; and the operation of turning a child, under the circumstances before stated, is rather to be considered among those things of which an experienced man may sometimes avail himself in critical situations, than as submitting to the ordinary rules of practice."*

In the second Volume of her "Pratique des Accouchemens," Madame Lachapelle relates the following instance of footling presentation in which the child was born with a depression of the parietal bone:—

Case XXIII.—A woman, pregnant for the second time, had a large accumulation of liquor amnii, and the child floated so easily in it, that when labour pains first supervened, the presentation altered from time to time. The membranes at last were broken, and the left foot descended. By dragging at this foot, the lower extremities and then the trunk passed with facility. The left arm, however, got fixed between the head and pubis, and was disengaged with some trouble. "The head, however," to quote the author's own account, "although directed transversely, offered still greater difficulties in its extraction, either because the pelvis was a little distorted, or because our efforts were not absolutely directed according to the axis of the brim. At all events it is certain, that after the birth of the fœtus we found a *considerable depression* on the right parietal bone, which had rested upon the sacro-vertebral angle. In despite of this lesion, the infant, which was at first apparently still-born, not only lived, but the depression was dissipated, and indeed was scarcely visible fifteen days afterwards. The mother did not experience the slightest bad symptom."*

Dugés has recorded two cases which came under his observation, in which the cranium was very deeply depressed and indented in the way described in the preceding instances, and yet both children lived and did well.

Cases XXIV and XXV.—In one of these cases of Dugés the frontal bone was so much *depressed*, that the left eye appeared as it were protruded from the orbit; still the child neither suffered from convulsions, nor any other special symptoms. In the second case the child had come footling through a pelvis, the great [congugate ?] diameter of which was estimated at three and a quarter inches. (*Dont le grand diamètre etait evalué a trois pouces un quart.*) The head could not at first be extracted by the aid, even of very strong tractions on the inferior jaw and shoulders, but scarcely were these artificial efforts momentarily suspended, when the head passed rapidly without assistance, and expelled by the action of the abdominal muscles. The left parietal bone which had pressed upon the promontory of the sacrum was *depressed and indented* to the depth of half an inch, and throughout an extent of two inches. Two or three spoonfuls of blood were allowed to escape from the vessels of the cord, which yet beat with sufficient force, although the infant was apparently dead; and betimes the child became gradually re-animated, and began to cry, and passed meconium. It was troubled with constant hiccup, puckering of the lips, and torsion of the mouth to the left side; spasmodic closure of the right eye, immobility of the left; rigidity of the hands; fingers extended, and separate, with the exception of the thumbs, and the last phalanx of one of the index fingers, which were flexed inwards; rigidity of the arms and limbs. These symptoms were remittent, and returned in fits at intervals of ten minutes. Two leeches were applied to the left temple. The fits continued during the evening and night, but gradually became less and less severe. On the morrow the infant drank; it took the breast the following day; and in fifteen days after birth the cranial depression had almost entirely disappeared.

In his "Manual of Midwifery," the same writer (Dugés,) observes,—"The bones of the cranium are often fractured with indentation, by the sacro-vertebral angle of the mother. It is one of the frontal, or one

* Introduction to the Practice of Midwifery, p. 382.

* "Pratique des Accouchemens," Vol. ii., p. 166.

of the temporal regions, which is the most common seat of these lesions. * * * These fractures often heal spontaneously; the indentations even rise in a few days."*

Jacquemier, one of the latest French writers on midwifery, and from whose work I have quoted Dugés' cases, states that these fractures of the fœtal cranium, with depression, are not by themselves a cause of certain death; "the depression," he remarks, "relieves itself by degress, and after ten or fifteen days, there scarcely remain any vestiges of it."†

If it were required I might cite other cases, and remarks of the same description from other authors, in evidence of the fact, that the state of compression and indentation of the bones of the infant's cranium at birth, is not necessarily fatal to the infant's life. Some additional proofs will be quoted in the sequel; in the meantime I have, I believe, stated enough to show,—*first*, that the neck of the child, if it be living, or only lately dead, is so strong, as to allow us to exert such a degree of traction upon the obstructed head, that the sides of the cranium may become greatly compressed, or even indented, under it; and, *secondly*, that Dr. Radford is truly wrong in stating that such a lesion and practice is incompatible with the safety of the child. On the contrary, the recorded experience of Velpeau, Chaussier, Smellie, Denman, Lachapelle, Dugés, Jacquemier, &c. &c., proves (as we have seen,) that the depression and indentation of the child's head do not necessarily destroy the child's life. Nay, Dr. Radford's own experience on this point is, I know, not in favour of his views, but of mine. In evidence of this I shall quote a case in point, recorded by Dr. Radford himself, from his own practice.

Case XXVI.—"I was requested," says Dr. Radford, "by Mr. Dick, to visit a poor woman in New Blakely Street, who was suffering from protracted labour, caused by contraction of the brim of the pelvis. The long forceps were applied, and the child delivered alive. *A depression of considerable size was produced on the left parietal bone*, from the pressure it had sustained from the promontory of the sacrum. The signs which the child manifested were those of apoplexy. The funis was divided, but no blood followed, as the pulsation had previously ceased. The child continued in the same state during the day, and in the evening was attacked with convulsions, which were frequent. Two leeches were applied to the temples, the bowels were opened, and the child recovered."‡

But further, argues Dr. Radford, such a procedure as I propose is "at variance with all *scientific* views." I shall not stop at present to debate here whether the practice I suggest be "scientific" or not; but in a medical point of view I hold that appellation to be truly merited by any propositions and measures that tend, like the present, to promote the great essence and object of all medical science,—namely, the preservation of human life; and in the various cases which I have quoted in the preceding sections, while none of the mothers were lost, the lives of the infants were at the same time all saved. But assuredly the heads of most of these children would have been opened by the perforator, and their lives thus destroyed, provided, in each instance, the structure of the cranium had not yielded, and its bony parietes become fortunately depressed, and indented to the degree required to admit of its safe transit through the contracted apertures of the pelvis.

CASE OF ACUTE LARYNGITIS,

WITH REMARKS ON DR. WARDELL'S CASES OF SPASMA GLOTTIDIS.

By T. OGIER WARD, M.D., Oxon.

In my last communication of an obscure case of sudden death, with enlarged thymus, I alluded to some cases of laryngeal affection, lately published in the *Provincial Medical and Surgical Journal*, by Dr. Wardell, respecting the nature of which I differed from the author; and I stated my intention to recur to the subject at a future period, and to describe a case that had recently fallen under my observation, which seemed to me, though identical in its symptoms with Dr. Wardell's alleged cases of spasm of the glottis, to be purely inflammatory.

November 25th, at 6 p.m., during the prevalence of the influenza, I was requested by a medical friend to take charge of a case during his unavoidable absence, which he considered so urgent that he dared not quit the house without leaving somebody in attendance. When I reached the place, I found the patient, a maid-servant, aged 20, lying in bed in a semi-recumbent posture; she was as red as scarlet, with a flushed and tumid face, bright and prominent eyes, distended nostrils, gasping for breath, and exclaiming in a whisper that she was choking. She was very restless, throwing her arms about, and tossing from side to side with vain attempts to relieve herself from the feeling of suffocation, and breathing with a stridulous sound, very audible as I ran up stairs. Her throat was bleeding from the bites of twenty-four leeches which had just been applied, and yet every moment the dyspnœa was increasing. I was told that she had caught cold at church the previous Sunday, but had taken no notice of it till 4 p.m., this day, when she was seized with sudden pain in the larynx, and dyspnœa, attended with extreme heat of skin, and rapid pulse—150. My friend being in immediate attendance, ordered twenty-four leeches to the throat, which had just dropped off when I saw her. Sensible of the urgency of the case, and that if she were not speedily relieved asphyxia must shortly occur, I determined to perform laryngotomy, if the remedies I proposed to use failed in their effects. I therefore returned home, and though I was not absent

ten minutes, I found on my return the danger still more imminent, the pain and dyspnœa having both increased.

I first gave her two grains of tartarized antimony in a little jam, which she swallowed with very great difficulty, making the same efforts as if she had a quinsy, though no affection of the throat was discoverable by the eye; and having waited some time, and finding no effect produced, I inserted a few grains of powdered alum into the tube of my caustic case, and blew them into her throat, which the alum readily entered during her efforts to inspire. Cough was instantly excited, and as soon as it had subsided I blew in more alum, with a similar result, until I had used about nineteen grains of alum at three insufflations. After the cough had ceased the third time, she said in a clearer voice that she was relieved, and began to breathe with more facility, the respirations falling from sixty to forty a minute, and the pulse sinking from 150 to 120. She now began to converse, and told me that the larynx was the seat of the pain, and that she felt a little thing of the shape of a heart in her throat that seemed to stop her breath. Soon afterwards the emetic began to act, she vomited freely, and in the course of half an hour she was out of immediate danger, though still suffering from pain in the larynx. Calomel and Pulvis Antimonialis, with saline mixture, were now ordered, and in a few days she completely recovered; but, so different was her appearance the morning after the attack, from the subsidence of the fever, and the removal of the expression of anxiety from her countenance, that I failed to recognize her at my visit.

If we now examine the course and symptoms of this case, there will be little difficulty in coming to a correct conclusion as to its nature. A girl catches cold during the prevalence of influenza, (which was frequently attended with pain in the larynx, and hoarseness and loss of voice,) and then is seized suddenly with acute pricking and burning pain in the larynx, attended with loss of voice and extreme dyspnœa, of a stridulous character, clearly indicative of a physical obstruction to the passage of air; while her own description of feeling a "thing like a heart" at the back of the throat, yet invisible to inspection, points as clearly to the epiglottis as the part she meant. This swelling of the epiglottis, together with the pain and tenderness of the larynx, and the general fever, are so different from the symptoms of spasm, that we cannot fail to recognize the presence of acute inflammation of the larynx, attended with œdema of the epiglottis and glottis.

It may, however, be objected, that the speedy relief induced by the insufflation of the alum is inconsistent with the removal of an inflammatory deposit such as œdema. But this lesion forms so rapidly in certain cases, that there can be little difficulty in admitting that it may be as speedily removed, particularly if we take into consideration the structure of the larynx, consisting of cartilages, partially covered with thin muscles, but mostly only by a mucous membrane, connected with the parts beneath by a lax areolar or cellular tissue, exactly similar to the texture of the eyelids,—except that the latter have one surface composed of cutis, while the former has both its interior and exterior surfaces, consisting of mucous membrane, at least around the glottis. Now, we continually see the effect of a blow, friction, or even the irritation of a little dust, in producing œdema of the eyelids, which subsides as rapidly as it has arisen, and therefore why may not the same result occur in the larynx from the direct application of a strong astringent, as alum? In cases of relaxed and œdematous uvula, we can see this effect produced by the action of an astringent gargle. Besides, in further proof of the inflammatory nature of the attack, although the dyspnœa was relieved, the other symptoms of inflammation, the pain, tenderness, fever, &c., still remained, though in a less degree, and did not entirely cease for three days. Hence I can come to no other conclusion than that the above was a case of acute laryngitis, with œdema of the glottis and epiglottis.

Let us now apply the same reasoning to Dr. Wardell's alleged cases of spasm of the glottis, for, coming from the note-book of a professed pathologist, they carry greater weight, and are deserving of more attention than would perhaps be the case did they record the ideas of a less practised observer.

Dr. Wardell sets out by stating that "these cases are not published as presenting features of very great rarity;" that "spasm of the glottis is but occasionally met with in adults,"—"nor was it until of late years fully understood." That such cases are not very rare we may judge, from the numbers that have recently been published in the medical journals since Dr. Wardell has turned attention towards them; and that even now they are not fully understood may be gathered from the fact, that though presenting the same features as Dr. Wardell's and my own, they are entitled cases of spasm of the glottis by their authors. Dr. Wardell's observation respecting their being only occasionally met with in adults cannot apply to these, and therefore, I would beg to be informed where we can meet with published cases of pure uncomplicated spasm of the glottis in the adult, as I have not been able during an extensive search, especially directed to this subject, to meet with a single instance. There are numerous cases of dyspnœa, spasmodic asthma, and angina pectoris in our medical records, and every man of experience can doubtless add to their number from his own practice; but pure spasm of the glottis is not met with in adults in England, whatever may be the case in the north; and that this may be so is not improbable, when we remember that infantile spasm of the glottis is almost unknown in France, probably owing to the greater dryness of the climate; and Messrs. Rilliet and Barthez, in their work on infantile diseases, borrow their description of it from the English authors. Further, I believe that every author who has written on the subject has admitted that great obscurities do surround the pathology of this disease.

The disease in Dr. Wardell's first case occurred in a girl aged 18, who had taken cold from wet feet, and began suddenly with dyspnœa and loud croupy inspiration, lasting 17 hours without intermission, but with slight remission, recurring again four hours afterwards,

continuing some time, and being attended with symptoms of a spasmodic character. The attacks ceased on the third day, having been combatted by bleeding to fainting at first, followed by hot drinks, and a full dose of morphine at bed-time. The treatment on the following days was a combination of opiates and antispasmodics, with counter-irritation.

The next patient, a boy, aged 16, had also got wet; his complaint began the next day with hoarseness, which was relieved by Linimentum Ammoniæ, and the ordinary treatment for a cold. Eleven days afterwards he had an attack of dyspnœa, with crowing inspiration, which lasted two hours, and was relieved by bleeding and opiates. It afterwards returned with violence, and was attended with convulsive movements of the limbs, and hard accelerated pulse, the patient being an epileptic subject. The treatment was similar to that of the former case, and proved successful the second day.

Now in regard to these cases, both of which were attended with febrile symptoms at the outset, I would ask what evidence have we of spasm of the glottis that may not as readily be adduced in proof of the inflammatory nature of the attack? Indeed, in a third case Dr. Wardell admits the existence of inflammation in the larnyx, and argues justly that the irritation had produced a spasmodic closure of the glottis. That there was a constriction of the glottis in these cases can hardly be doubted; but, as Dr. Wardell must be aware, that true spasm or closure of the glottis, from whatever cause, cannot continue for more than a few seconds without being followed by death, it is to be regretted that he should have given us these interesting cases under the title of spasm of the glottis, and that in his observations upon them he should have endeavoured to identify them with the infantile complaint. It would have been better had he imitated the reserve of that excellent pathologist, Dr. Copland, who does not admit any disease under that name into his Dictionary of Medicine.

I cannot pass over one of the observations of Dr. Wardell, published in the *Provincial Journal* for October 20th, as it is even more calculated to mislead than the cases themselves. It is as follows:—"It has been said that cold and damp have nothing to do with the production of laryngismus stridulus, and that croup on the contrary, is mainly brought on by these conditions. It is quite clear from the above cases, that the first of these statements is incorrect, as in both instances wet and cold were the exciting causes." Besides the *petitio principii* involved in this sentence, did it never occur to Dr. Wardell, that they might be very reasonably considered as cases of laryngitis, or œdema of the glottis, or other inflammatory disease? I conceive also that Dr. Wardell has failed in his endeavour to prove the existence of any hysterical affection in either case in support of the spasmodic character of the attacks. The girl exhibited none except when "choking," and the wonder is that the boy, an epileptic subject, was not more convulsed during the attacks.

There are several other remarks that might admit of discussion, but I pass them by as not relevant to my present purpose. In what I have stated with regard to these cases I have no wish to detract from Dr. Wardell's merits of close observation and appropriate treatment; but believing that pure spasm of the glottis does not occur in the adult, or at least has not yet been described, I cannot but object to these cases being brought forward as instances of it, particularly has they have led to the publication of similar ones by other parties, to which the above remarks are equally applicable. The purely spasmodic disease of children has already received almost as many names as it has met with describers, and if other complaints of the respiratory organs which have only one symptom (viz., the stridulous breathing,) in common with it, are to be classed under the same head, neither the nosology nor pathology of spasma glottidis can ever be established on a secure basis.

Kensington, Feb. 25, 1848.

SHORT NOTES OF THE OPINIONS AND PRACTICE OF THE LATE JOHN PEARSON, ESQ., F.R.S., ON SYPHILITIC DISEASE.*

By W. S. Oke, M.D., Physician to the Royal South Hants Infirmary.

Venereal Ulcerations.—These are of two kinds. The first is a circular ulcer, chiefly found on the shoulders, back, or abdomen. It seldom exceeds three inches in diameter, and is rarely less than two. It forms a regular circle, having an area within it of sound skin. As its depth does not extend to the cellular tissue, it may be called a superficial ulcer, and it probably arises from a spot. When these ulcers occur, they may be considered as a proof of the long continuance of the disease. They do not appear to arise from the skin glands.

The second kind is an ulceration which attacks the toes, and is much more serious than the first, having sometimes proved fatal. This is a deep, painful, and ill-conditioned sore, discharging an offensive ichor, of a dark colour. It will sometimes extend around the foot; and if the under part alone be affected, the ulcer generally occupies the whole angle between the foot and toes. As the sebaceous glands abound in these parts, it may be presumed they are involved in the disease. This ulcer is seldom seen but in hospitals, and in persons very inattentive to cleanliness.

Treatment of Ulceration between the Toes.—These ulcers require great attention: in an early stage they will often heal with common dressing and Bates's camphorated water, considerably diluted. This wash answers better than those of mercury. When the ulcer spreads extensively, and becomes foul and painful, the fermenting poultice, made in the following manner, may be tried with advantage:—"Let flour be mixed with honey till it becomes of the consistence of dough,

* Continued from page 123.

and then a sufficient quantity of yeast may be added. The mass should be placed before a fire till it begins to rise, when it may be applied, in order that the fermentation may go on upon the ulcer." Opium, bark, and sulphuric acid, should be given internally; and if the opium should not give ease, the Extractum Conii may be substituted in large doses, beginning with five grains three times a day, and gradually increasing the dose till giddiness is produced. The extract of conium, though an uncertain remedy, should not be neglected; it is often found to succeed better than other narcotics. The Extractum Stramonii has been tried in these cases till it began to produce its poisonous effects, viz., tremors and flashes of light passing before the eyes, and general disturbance, but without success.

Venereal Ulcers on the Tongue.—These are by no means common in syphilitic disease. This morbid alteration generally begins rather beyond the middle of the tongue, in the direction of the central line. It appears first as a soft tubercle, and enlarges in length towards the base of the tongue; the edges have a sort of mulberry appearance, and the ulcer discharges an offensive matter. Sometimes the edges of the tongue, the uvula, or arches of the palate, have an excoriated or aphthous appearance. These symptoms sometimes occur without any other venereal symptom, but they are more commonly in association with blotches on the skin. At other times there will be an ulcer on the side of the tongue, with callous irregular edges, accompanied with sore-throat; or a sore on the tip of the tongue, with smooth callous edges, very painful, especially during the night; or there may be tubercles on the side of the tongue, resembling those which appear on the inside of the thighs and scrotum, when they excoriate each other.

[Mr. Pearson states that he has not seen more than six indisputable cases of venereal ulcers on the tongue. I have, myself, seen two well-marked cases. The first occurred in a young man admitted into the Royal South Hants Infirmary. It consisted of a soft tubercular mass, considerably elevated, of an ovoid shape, mulberry colour, situated upon the centre of the middle line of the tongue, and occupying half its length. The second was that of a young man, 25 years of age. It was a large and deep ulcer on the right side of the tongue, discharging an offensive matter, and so extremely painful as to prevent mastication. Both these cases were speedily and completely cured by five grains of the Pilula Hydrargyri every night, and five grains of the iodide of potassium, in solution, three times a day. I have also seen a syphilitic sore on the lower lip, of a middle-aged man, somewhat analogous in appearance to the former of the above cases: it had grown to a projecting mass of a loose texture, of a deep red colour, and of the shape and size of a large walnut. It was proposed to extirpate it by excision, but by the use of the iodide of potassium, and the compound decoction of sarsaparilla, it soon got well.]

Tertiary Symptoms—[Called by Mr. Pearson the second class of secondary symptoms.]—As the venereal disease advances further into the system, and affects parts differing in structure and function, it puts on a different appearance. When admitted into the blood-vessels, its morbid effects are prodigiously multiplied, and are chiefly confined to those parts exposed to the air.

The secondary symptoms are often seen to remain stationary for a time, and if too small a quantity of mercury be used, the same symptoms may return again and again without proceeding into the tertiary.

In the secondary symptoms the powers of the constitution may be sufficient to cause the eruption to disappear, but in the tertiary symptoms the constitution does not seem to possess the same remedial power. In this stage of the complaint the general health suffers more than in the earlier stages; the complexion loses its normal colour, and assumes a sallow leaden hue; there are frequent shiverings, wandering pains, and general uneasiness; the pulse is frequent; there are profuse night sweats, great emaciation, and, not unfrequently, œdematous swellings of the ankles and feet; the tongue often remains clean, and the appetite good. At other times there is a disinclination for food, with sickness, bringing up a ropy mucus from the stomach, to the amount of, in some cases, a pint at a time. There is sometimes hoarseness and complete loss of voice.

Tertiary symptoms may be divided into two species:—1st, affections of the skin and membranes; 2nd, morbid alterations of the bones.

Affections of the Skin and Membranes.—In this stage the eruption is generally pustular, larger than variolous pustules, deeply seated, not rising much above the surface, and of an orange or light-red colour, with a hair generally in the centre. It soon becomes covered with a white crust, which gradually assumes a darker colour; then the adjacent parts are involved, and the whole has somewhat the appearance of carbuncle, leaving deep and foul ulcers, which are very painful. These pustules vary in size (from the size of a split pea to that of the palm of the hand,) and are met with chiefly on the arms, neck, face, and shoulders. The forehead and nose are sometimes seen covered with four or five large crusts, projecting two or three inches from the surface, and looking like horns.

The ulcers are disposed to produce fungus very quickly, and leave deep and indelible cicatrices behind. The ulcer often appears as if the part had been scooped out, having thickened edges, and discharging an offensive and sanious matter. It has been mistaken for cancerous disease.

[In the summer of 1846 I met with an instance of

this kind. A married woman, of middle age, had a large deep ulcer on the left ala of the nose, which disfigured her face exceedingly. It had existed for nine months, and resisted every means prescribed for its cure by various medical men. The edges were raised and thickened, the surface foul, the discharge sanious, and the adjacent skin of the ala discoloured and swollen. At first sight I considered the case to be carcinomatous; but, being reminded that a few years previously she had been under my advice for ulcerated sore-throat, a light was at once thrown upon its true character. Five grains of blue pill were now ordered every night, and four grains of the iodide of potassium three times a day, dissolved in peppermint water. In one month the ulcer was completely healed, and all disfigurement removed.]

It is somewhat extraordinary that there should not be a tendency in the absorbent system to be affected again by these ulcers or pustules in like manner as they are affected by a primary sore, when they so readily carry the virus into the next absorbent gland; this may arise from the matter formed in an advanced stage of the disease being different from that of the primary sore, or from its being in a diluted state; but it is not easy to arrive at any absolute conclusion on this point. At the same time it is important to ascertain whether the fluid from a tertiary ulcer can communicate the disease to a sound person. There are no facts to prove that the constitution possesses the natural power to render the virus innoxious to the patient himself. The matter of a chancre is certainly the most active; that of a bubo is much less so; and that arising from eruptions and nodes still less active: but in the last even it is sufficiently powerful to produce a series of symptoms, which, if neglected, will finally destroy the patient.

Tertiary sores are so seldom situated on the organs of generation, that it is difficult to decide their character, when sores apparently of this kind *are* found there, either from patients generally giving incorrect accounts of themselves or from having an interest in misstating their case in order to conceal the cause of their being possibly of a more recent date. When tertiary sores really exist on the genitals, the discharge is generally so great as to dilute the virus and render infection much less certain than from the discharge of primary sores.

It has been observed, that the symptoms, which precede the appearance of the secondary eruption, are not very dissimilar to the eruptive form of small pox, and that when the eruption appears the fever declines; but the constitutional disturbance in the *tertiary* class is much more permanent, and is not relieved by the eruption.

The patient continues languid, especially when he rises in the morning; has a sallow and leaden aspect; wandering pains; profuse night sweats; vomits a ropy mucus, and is occasionally affected with hoarseness.

This may be called "erethismus syphiliticus," produced by the irritation of a morbid poison. It has frequently been mistaken for hectic fever, and greatly aggravated by the treatment, whilst all the symptoms have been relieved by the proper administration of mercury. Whenever, therefore, a patient, who has had the venereal disease, of which but *few* marks remain, complains either of wandering pains, headache, soreness of the throat, or loss of voice, the symptoms are to be suspected of being the result of lues,—at any rate they require to be traced attentively to their origin.

Enlargement of the Ligaments of the Joints, and Affections of the Bones.—This is not a frequent symptom, yet it is sometimes to be met with. The joints most frequently affected are the ankles, wrists, and sometimes the elbows. Here there is a different affection from that attacking the joints during a course of mercury, in which the middle joints of the fingers, the joints of the elbows and ankles, &c., are sometimes tumefied, and have puffy or livid appearance. This case is frequently attended with a good deal of pain, and a bad state of health, which seems to threaten the patient with consumption. When the ossa malorum or alveoli of the lower jaw are affected, the result is generally fatal; and is to be attributed to the mercury and never to the venereal disease.

The periosteum is the membrane most frequently affected by the venereal disease, and at first the subjacent bone is not involved in the disease; but as diseased bone is often the result of a morbid condition of the periosteum, both are sometimes found involved.

When the venereal virus attacks the bones of the head, the centre of the parietal bones will be found most commonly the seat of the disease, and the frontal bones will be affected at about the roots of the hair.

The malar bones and the nasal, are not often attacked—indeed the latter are but very seldom if ever destroyed by the venereal virus, though very often by the abuse of mercury. The horizontal plate of the superior maxillary bone, the vomer, the cancelli of the ethmoid bone, and the inferior spongy bones, are most frequently attacked by the venereal disease.

The radius and ulna are seldom affected by it, and then only in old cases; the tibia is usually attacked at its lower extremity; and the fibula is generally exempt, except sometimes at an advanced stage of the disease. The bones of the hands and feet do not suffer from the venereal virus; and it is not certain that caries of the clavicle, sternum, or ribs ever proceed from this cause; these bones suffer more commonly from scrofula, although the affection may subside under the use of mercury. [I once saw the greater part of the sternum necrosed by struma.]

Venereal Nodes.—When the periosteum is attacked there is acute pain, which exacerbates in the evening, and is much increased by pressure; there is generally some redness externally, and the membrane is always

thickened, accompanied by the formation, of a glairy fluid, or a semi-coagulated mass. Many weeks may elapse, if the inflammation be chronic, without the secretion of pus; and previously to this, the bone is seldom diseased; but if the periosteum be much separated, the bone will probably become carious.

The pain occasioned by this form of the disease is the most acute that can be endured,—the patient is prevented from having any sleep, and sometimes becomes delirious.

The progress of the disease is various. The part may acquire a prodigious thickness, without any matter being contained; or the fluid may be effused between the periosteum and skin, proceed rapidly, and not be attended with much pain. This is called the spurious node, and is found upon the forehead and upper part of the tibia; again, the matter may be under the periosteum, and then the pain is most severe. The abscess proceeds but slowly, and seldom opens spontaneously. The rapid increase of size occasionally observed, is not owing so much to the virus itself as to the matter acting as an irritant; this case will occasionally subside in as rapid a manner as it took place.

(To be continued.)

CASE OF FRACTURE OF THE SUPERIOR MAXILLA, WITH DISPLACEMENT OF THE MALAR BONE.

By Hugh R. Rump, Esq., M.R.C.S.E., Wells, Norfolk.

Robert C., aged 25, a seaman, tall and muscular. On Sunday, the 9th of January, 1848, whilst driving at a rapid pace out of an inn yard, the wheel came in contact with the gate post, by which means the gig was upset, and its driver dashed with great violence upon the hard and frosty road, alighting on his face. When first visited, he was suffering from concussion of the brain, was very pallid, and the skin bedewed with perspiration; he made frequent ineffectual attempts to vomit, and although very drowsy and lethargic, replied rationally, when interrogated in a loud and distinct voice. The pulse was small, quick and irregular; and the extremities were cold. The right side of the face presented a very peculiar appearance; the natural prominence of the cheek had disappeared, whilst the globe of the eye was forced upwards and slightly outwards; there was a superficial wound on the cheek, and the eyelids were tumid and ecchymosed. Upon making an examination, (both externally and within the mouth,) a fracture was immediately detected in the superior maxillary bone, extending from its orbitar surface downwards through the canine fossa, then taking a direction backwards and downwards, below the malar process of the bone and continuing its course, through the maxillary tuberosity. The malar bone, together with the malar process of the maxilla, was driven upwards and inwards, towards the internal angle of the orbit; and projected upwards above the floor of the orbit nearly a quarter of an inch, so that its circumference was considerably diminished. By carefully tracing the finger along the zygoma, a depression could be recognized at its articulation with the malar bone, a space intervening between the two bones. No lesion of the fronto-malar articulation could be detected.

As all attempts to reduce the fracture and to place the bones in situ proved abortive, the patient was put to bed, wrapped in blankets, bottles of hot water were placed to the feet, a cordial stimulant administered, and a water-dressing applied to the wound.

January 10th. Had no sleep during the night; was very faint, and vomited two or three times. Complains this morning of great numbness of the right side of the head, and has lost all sensation in the upper part of the cheek, or in those parts supplied by the supra-orbital nerve; and in the gums and teeth, as far as the mesial line. Smart febrile re-action has commenced; the face is flushed, and the soft parts about the seat of injury are very swollen and ecchymosed; tongue furred and dry; pulse 86, full, but compressible.

To take five grains of calomel, with ten of extract of colocynth directly; a saline draught every three hours; a dozen leeches to be applied to the cheek, and subsequently water-dressing.

21st. Is convalescent; the only inconvenience resulting from the accident is loss of sensation in part of the cheek, side of the nose, gums, and teeth. Returns to his duty to-day.

Observations.—Fractures of the bones of the face are acknowledged by all surgical writers to be of comparatively rare occurrence, and they are all equally agreed, as to the difficulty, and in most cases, the impossibility, of their reduction,—it not being "practicable in these cases, as in fractures of the limbs, to operate by any mechanical power upon one or other of the fractured extremities, for the pupose of reducing them to their normal relative position,"—and that unless the fracture be compound, and great inconvenience and danger be apprehended from detached fragments of bone, it is far better to suffer the fractured bones to remain displaced, than to seek by operative means, to remove the deformity resulting from such accidents, the risk being too great from the division of the soft parts, and the possible benefit to be derived therefrom too inconsiderable, to warrant such procedure. In the above case considerable deformity exists, from the diminution of the orbit by the fractured bones projecting above its floor; but although the fracture extends through that part of the bone from which the inferior oblique muscle arises, every movement of the eye is accurately performed and vision remains unimpaired. The levator palpebræ muscle not being capable of elevating the lid sufficiently for the present position of the globe, is assisted by the occipito-frontalis, giving the patient the appearance of having undergone the operation for ptosis. From repeated and very careful manipulations, I am inclined to believe that the depression felt at the temporo-malar junction, was the result of disarticulation, and not of fracture. As both the anterior and posterior dental

branches of the second division of the fifth nerve are implicated by the fracture, it will be interesting to observe hereafter, whether the teeth become carious from defective innervation.

CASE OF LITHOTOMY: THE CALCULUS WEIGHING SEVEN OUNCES.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I request you will favour me by inserting in the *Provincial Journal*, the following (to me,) extraordinary case of lithotomy, and I shall feel obliged to any of my brethren who will inform me through the same channel, whether there be a similar case on record in one so young, as I am inclined to think it unique in the annals of surgery.

I am, Sir,

Your obedient servant,

GEORGE BULLEN.

Ipswich, March 5, 1848.

On Thursday last, I operated with a common director and a straight bistoury, upon Sophia Cooper, 14 years of age. I extracted a calculus weighing *seven ounces*. This enormous mass was of course broken into many pieces. Seven portions, each as large in size as an ordinary calculus, were removed by the forceps, some with considerable difficulty from their ragged edges becoming entangled in the soft parts. The smaller fragments were extracted by the scoop.

I was fortunate enough after the operation to be able to adapt the fragments so accurately as to make the stone complete. It is composed of oxalate of lime, with a nucleus of uric acid, and measures round its largest circumference eight inches and a half, and round its smallest six inches and three quarters, and is about the size of a swan's egg.

Up to the present time, I rejoice to say, my patient has progressed without one untoward symptom.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, MARCH 22, 1848.

In our last number we alluded to a general measure of Medical Legislation which had been agreed upon by a Committee of the Royal Colleges of Physicians and Surgeons, the Society of Apothecaries, and the National Institute of Medicine, Surgery, and Midwifery. The propositions agreed to as the heads of this measure as they appeared in a contemporary Journal were also published in another column. We have since received an official copy of the document, and as the subject is of the deepest interest to the whole profession, and the official copy differs in some degree from that before published, we believe we shall be consulting the wishes of the members of the Provincial Association, by here laying the entire measure before them in an authentic shape.

PRINCIPLES ON WHICH A BILL FOR REGULATING THE PRACTICE OF PHYSIC AND SURGERY SHOULD BE FOUNDED.

I. *New Incorporation.*—That a Charter of Incorporation should be granted to the Surgeon-Apothecaries of this country, under the title of "The Royal College of General Practitioners of England."

II. *Establishment of a Council.*—That a Council should be established to superintend the Registration of all Medical and Surgical Practitioners, and for the general control of Medical Education and Practice.

That the Council should consist of one of Her Majesty's Principal Secretaries of State, in right of his office, (who should also be President of the said Council, with power to appoint a Vice-President,) and that the other Members of the Council (of whom not less than two-thirds should be registered members of the Medical Profession,) should be such persons, not more than twelve, whom Her Majesty, with the advice of Her Privy Council, should deem fit to be members of the said Council.

That the Council should be empowered, with the approval of the Secretary of State, to appoint a principal Secretary, and local Secretaries for Scotland and Ireland, and Clerks, Messengers, &c.; and that the Members of the Council, the Secretaries, Clerks, &c., should receive such salaries as the Lords of the Treasury should think proper to allow.

III. *Register to be made and published.*—That a register should be made and published by the said Council, as soon as conveniently may be, of all persons entitled, as after explained, to be registered as Physicians Surgeons, or General Practitioners, and who shall apply to be so registered within one year if residing in any part of the United Kingdom, or within two years if resident abroad; for which a fee of Ten Shillings shall be paid by each person so registered. And that to the Register should afterwards be regularly added the names of all persons who shall receive Letters Testimonial, as after explained, of their fitness to practise as Physicians, Surgeons, or General Practitioners; and that for such registration should be paid the sum of Five Pounds in the case of a Physician or Fellow of the College of Surgeons, and of Two Pounds in the case of a General Practitioner. All such fees should be applied towards defraying the expenses of this Act.

The Register to be formed on the plan of a specimen submitted to the Committee of the House of Commons in 1847, by the Registrar of the College of Physicians.

And all persons desirous of being continued on the Register, should be required to send their names and residences to the Council, annually, but without the payment of additional fees.

The Register to be received as evidence in Courts of Law.

IV. *General Practitioners.*—That those persons should be entitled to be registered as General Practitioners, who shall be enrolled as Members of the Royal College of General Practitioners within one year from its first Incorporation, according to the provisions of a Charter which has been prepared for that College; and that those persons should afterwards be entitled to be so registered who, having attained the age of twenty-two years, shall have received Letters Testimonial of their

fitness to practise as General Practitioners, from the examining Board of the Royal College of General Practitioners, and who shall also have been examined and admitted as Members of the Royal College of Surgeons.

Surgeons.—That those persons shall be entitled to be registered as Surgeons, who shall have been admitted as Fellows or Members by the Royal College of Surgeons. That the Members of the College of Surgeons who dispense medicines, or supply medicines to their patients, shall be required to enrol themselves in the College of General Practitioners, and to be registered as Surgeons and General Practitioners; and after the passing of the Act, Members of the Royal College of Surgeons shall not be registered as Surgeons unless they be also admitted as Members of the Royal College of General Practitioners, and registered both as Surgeons and General Practitioners.

Physicians.—That those persons should be entitled to be registered as Physicians, who shall have been admitted as Members of the Royal College of Physicians, according to the provisions of a new Charter which has been prepared for the College of Physicians, and has also been submitted to the Government, which Charter it is expedient should be granted to the College of Physicians.

Registry of Special Cases.—That the cases of persons who have been engaged in practice prior to the passing of the Act, without being Members of any Corporate Body in the Profession, should be referred to the College of the department in which they have practised respectively, for special investigation of their claims to be admitted to register.

V. *Reciprocity of Practice.*—That the Members of each class of the Profession, registered in each of the three kingdoms respectively, should be entitled to be registered and to practise reciprocally in either of the three kingdoms as Physicians, Surgeons, or General Practitioners, as the case may be, provided the education and examinations of each class respectively, be assimilated and regulated by a certain standard common to each class; and provided that, previous to registration, they be enrolled in the College appropriated to their class, in the country in which they practise.

VI. *Powers of the Council as to Bye-Laws.*—That the Council shall be empowered to allow or disallow any new Bye-law which shall be made by either of the Colleges.

Registry of Students.—Also, to cause a Register to be made of Medical and Surgical Students, and to make such dispensing regulations as shall seem fit in favour of those Students who shall have commenced their professional studies before the passing of the Act.

Returns of Fees, Examinations, &c., for securing Uniformity and Efficiency of Examinations.—Also to call for Returns respecting Examinations, and Fees for Letters Testimonial and Admission into the respective Colleges, and to take such other measures as may be necessary in order to assimilate, as nearly as possible, the education, examinations, and fees for each class of the Profession, respectively, in each of the three Kingdoms. And that the Council should be empowered, in any case in which it should appear to be necessary, in order to secure efficiency and uniformity of examinations, to depute one or more of its members to be present at the examinations of any of the Colleges; provided the Members of the Council so deputed be Medical Practitioners, and of the same class in the Profession as the College to be so visited; and if, upon the Report of such visitor, or otherwise, the Council should be of opinion that its regulations are not complied with by any examining body, that it should be lawful for the Council to refuse to register upon the Testimonials of the Body so in default, until the same be amended to the satisfaction of the Council.

As to Striking from the Register.—That the Council should be empowered to strike from the Register the names of any persons who shall be proved to have obtained the registry of their names by any fraud or false certificate, or who shall have been convicted of felony, or of having wilfully and knowingly given any false certificate in any case in which the certificate of a Medical Practitioner is required by law; also, the names of any persons who shall have been expelled from either of the Colleges, according to the terms of their respective Charters, provided such expulsion shall have been approved and allowed by the Council, as before required, respecting Bye-Laws.

VII. *Privileges of Persons registered.*—That no one who is not registered should be judged capable of performing any act which is required by law to be done by a Medical Practitioner; nor should any but a registered person be appointed to any office which is deemed by the Council to be a public Medical or Surgical office; nor should any but registered General Practitioners be entitled to demand or recover fees for Medical and Surgical advice and attendance, or for medicines prescribed or administered.

VIII. *Penalties on Unqualified Persons, and for false Pretences of Qualification.*—That penalties should be imposed by summary process on all unregistered persons practising Medicine or Surgery.

Also, on all unregistered persons falsely pretending to be registered.

Also, on all Persons assuming any professional name or designation to which they are not by Law entitled, or which implies that they belong to a class in the Register in which they are not registered, or that they are Members of a College in which they are not enrolled.

In thus laying down the principles on which a Bill should be framed for regulating the whole Medical Profession, the Committee has entered into particulars only as regards the Profession in England; but, under the fifth head, respecting reciprocity of practice in the three kingdoms, it has assigned the conditions which are clearly indispensable for the attainment of that desirable object.

The Committee is aware that some variations from the plan which is here drawn out for England may be rendered advisable or necessary, by local circumstances and the rights of existing institutions, in Scotland and Ireland.

And the Committee is contented that such variations should be made, provided the principle be not contravened, that equality of Education and qualifications in each class respectively of the Profession in the three kingdoms should be first obtained, in order that the right of reciprocal practice may be justly allowed.

(Signed,)

J. A. PARIS,
President of the College of Physicians.

BENJ. TRAVERS,
President of the College of Surgeons of England.

EDW. BEAN,
Master of the Society of Apothecaries.

R. R. PENNINGTON,
President of the National Institute.

February, 1848.

We have no intention of criticising the several clauses of the foregoing document, but as it is evident that a number of gentlemen, members of the College of Surgeons, can have

had but little opportunity of being consulted in this measure, we feel ourselves called upon to direct their attention to the clauses which more especially concern their body. In our last number the Council of the Provincial Medical and Surgical Association appealed to the physicians of England resident in the provinces, to express their opinions on the proposed Charter to be applied for by the Royal College of Physicians in connection with this measure, with the intent that such objections as may be entertained might be brought under the notice of the College. We are now authorized to state that the Council of the Association are equally desirous of learning the opinions of those members of the Royal College of Surgeons who may consider their interests not to be sufficiently represented in the conferences which have recently taken place, with the view of ascertaining and making known in like manner, in the proper quarters, the objections which may be entertained to any of the provisions of the contemplated measure.

Before concluding these remarks we beg to express our conviction that the Joint Committee have been influenced by the sincere desire of accommodating differences and obviating difficulties in the best manner that existing circumstances will permit. Their exertions are entitled to our respect and gratitude, and in calling for an expression of opinions on the subject, we are desirous of giving effect to the general principle of the measure which they have drawn up, by pointing out any objections which may be generally and strongly felt to certain portions of it, so as to induce them to adopt such modifications, should any be thought desirable, as may obviate opposition hereafter.

Notice.—It is requested that the Members of the College of Surgeons in general practice, and residing in the provinces, will communicate their opinions in reference to the clauses of the proposed measure on medical legislation, to the Council of the Provincial Medical and Surgical Association.

R. J. N. STREETEN, M.D.
Secretary to the Association.

Reviews.

Metropolitan Sanitary Commission. Second Report of the Commissioners appointed to enquire whether any, and what, special Means may be requisite for the Improvement of the Health of the Metropolis. 1848.

Is there any disease concerning the treatment of which each of us has less settled opinions as to the course he should pursue, than in that of Asiatic cholera, supposing it were again to visit us? On the other hand, what disease is more amenable to our remedies than diarrhœa? The treatment recommended in Asiatic cholera, is opposite and discordant, varying from bleeding to brandy,—from croton oil to opium,—from cajeput oil to cold water. That of diarrhœa is simple; aromatic confection, chalk mixture and opium, as a general rule, effectually relieves it. Asiatic cholera is the opprobrium of our art; the treatment of diarrhœa is almost as certain as if medicine was an exact science. But it is eminently satisfactory to those who love their profession, and feel deeply and conscientionsly that their art has a great and most useful power over disease, to find that Asiatic cholera, like consumption, is only incurable when fully formed, and that it has an early stage which is amenable to a fixed treatment. This stage is diarrhœa.

The Sanitary Commissioners have again brought forward the evidence on which this is founded, and we feel that we are doing our profession an important service, by circulating among them what otherwise would be chiefly read by members of parliament.

During the visitation of Asiatic cholera in 1832, it was very fatal at Bilston. Out of 14,700 inhabitants, 3568 were attacked, of whom 792 died in less than seven weeks,—one quarter of the whole population were subjects of the disease, and one fifth of those attacked died. Hear what the clergyman said:—

"The pestilence continues its ravages amongst us in a frightful manner. Our necessities are increasing every hour, and our resources are fast failing us. Three hundred pounds have been granted to the Board of Health out of the poor-rates; but this sum will not pay for the coffins of the dead. All kind of business is at a stand. Nothing reigns here but want and disease, death and desolation. Two of our medical men have perished; two more have left the place to recruit their exhausted strength; and my respectable neighbours are nearly worn out by mental anxiety and exertion."

In this extremity the Privy Council were applied to, who immediately sent down Dr. Mc'Cann, (since dead,) who had seen much of the disease in India.

Dr. Mc'Cann was convinced that looseness of the bowels is the premonitory symptom of Asiatic cholera, and that the effectual way of stopping the progress of the disease is to arrest this simple diarrhœa by the ordinary remedies. "The first thing he did was to

open a dispensary; to secure the attendance of medical men there night and day, and to placard the town with notices that, whoever was attacked with looseness of the bowels, might receive gratuitously, at this institution, instant advice and relief. Two assistant surgeons paid by the Board of Health were in constant attendance, and the resident surgeons of the town, three in number, undertook to visit the institution daily at regular intervals."

The effect was striking. In one week the mortality was reduced one half.

From June 20th to August 26th—275 deaths.

On the 26th the Dispensary was opened.

From August 26th to Sept. 2nd—132 deaths.

During these eight days 1100 personal applications were made for bowel complaints and attended to. In the next seven days there were 44 deaths, (one third of the number in the previous week;) 130 patients applied daily for relief. In nine days from this period the disease was extinguished.

By similar means under the same superintendence, a similar result was produced at Wolverhampton, where cholera was very extensively prevailing.

Mr. Hodgson, who was appointed by the Government on the Cholera Board of Health at Birmingham, and consequently paid great attention to the disease, was acquainted with what was going on at Bilston, and subsequently conversed with Dr. Mc'Cann on the subject. Mr. Hodgson has given it in evidence that he believes Dr. Mc'Cann's proceedings furnish a key to the treatment; and that to him is due, not of having first said that there is a premonitory stage, but having insisted on this point,—that there is a stage at which the disease may be readily stopped, but if it gets into the other stage, there is no known treatment to be relied on. Dr. Mc'Cann told him that he never knew a single instance of any person who had the second stage, who had not (perhaps only slightly,) the premonitory one; and Mr. Hodgson found, on conversing with nearly all the medical men who watched the treatment at Bilston and Wolverhampton, that they unanimously agreed in opinion as to the importance and efficacy of Dr. Mc'Cann's views and proceedings. "I have always felt (says Mr. Hodgson,) since that time, so far as my knowledge of the matter went, that if cholera ever threatened this country again, it would be a very manageable disorder, provided Dr. Mc'Cann's ideas were fully explained and acted upon, namely, that cholera consists of two parts—the premonitory condition, and the condition of collapse; and that, if you catch the disease in the premonitory condition, you may stop it at once, but that when it comes to the other condition there is great danger."

When questioned as to this premonitory stage, he said:—

"Any deviation from the usual healthy action of the bowels on the side of diarrhœa, I should regard as the early stage, as it were the blossom of the disease." So that if a person was accustomed to have only one evacuation a day in a solid form, and that were changed into a loose state, you would still regard that as a premonitory symptom? "I should."

The plan adopted at Birmingham he thus explained:—

"I have now by me some of the packets of medicines which were given gratuitously to the poor, and at a small cost to others. Various stations were appointed in the town from which these packets were distributed. Each packet contained three boluses, and each bolus consisted of twenty grains of opiate confection. The patient was directed to take one bolus every hour in a little warm water, or weak brandy and water, until the relaxation of the bowels ceased. Also in each packet there was a small bottle of strong sal volatile, of which a teaspoonful was to be taken in warm water, frequently, if the patient was cold, faint, or exhausted. Printed directions, as to the use of these remedies and other matters, were enclosed in the packets, and the patients were strongly urged to apply immediately for medical advice."

The plan which Dr. Mc'Cann himself followed, is explained by a relative, Mr. N. Mc'Cann:—

"Where only a slight looseness of the bowels existed, with or without pain, he gave at once a small dose of calomel, with rather a large one of opium; if the dejections continued, he administered the chalk mixture, combined with aromatic confection, ammonia, and tincture of bark; if the contrary effect were produced,—namely, constipation, small doses of castor oil were prescribed, to regulate the bowels. An embrocation of heated turpentine and laudanum was at the same time rubbed over the chest and abdomen, as a counter-irritant and sedative."

These views are in accordance with the practice in the Indian army. When cholera is raging every soldier has positive orders to report himself sick (says Dr. Parkes,) if he has any symptom of bowel complaint. The opinions of the Russian physicians at the present time are also in perfect accordance. In all the accounts from Russia received by the Sanitary Commissioners, "the medical men who are treating the epidemic which is now prevailing, first and prominently urge, '*that the greatest attention must be paid to the diarrhœa which precedes cholera.*'"

This plan is so remarkable, so accordant with the sage maxim *obsta principiis*, so confirmed by satisfactory evidence, as well as by the opinion of one whom it would be supererogatory to praise in this Journal,—Mr. Hodgson, of Birmingham,—that we give greater publicity to it with satisfaction. We would not affirm that these means will stop the earliest cases, which all evidence seems to prove are the most fatal, and the least amenable to any means, but that they will greatly diminish the mortality if energetically followed out, there can be no reasonable doubt, after this evidence.

Medical Portraits.

We beg to direct attention to the series of admirable portraits now in course of publication by Mr. T. M. Stone, of the Royal College of Surgeons. The portraits are published by subscription, and we understand it is the intention of Mr. Stone to continue the series so long as he meets with sufficient encouragement; not with any view to profit, but with the praiseworthy object of forming a uniform collection of portraits of those members of the profession who have been, and are, daily contributing to the advancement of medical and surgical knowledge. Those hitherto issued are two capital likenesses of Professor Fergusson, and Dr. Todd, of King's College Hospital, and a third of Mr. South, which we have not yet seen, has since appeared. They are drawn on stone by Mr. Maguire, and if continued in the same style of excellence, the undertaking cannot fail to meet with success. We are glad to learn that the provincial physicians and surgeons will not be forgotten in the series.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

COMMUNICATIONS.

[The following communications have been forwarded by Mr. Crompton.]

From James Barton Hilton, Esq., Surgeon, Swinton, near Manchester.

In accordance with your wish, I gladly furnish you with such information as I possess respecting the treatment of burns. In doing so, I have nothing novel to suggest; but circumstances having thrown more than an ordinary share of this description of practice in my way, I presume that to have been your motive in soliciting a contribution from me.

Having been in practice for nearly seventeen years in a neighbourhood where explosions of carburetted hydrogen gas frequently occur, I have had abundant opportunities of seeing cases of burns, and for the last six years I have attended all the cases occurring in the collieries in this district, belonging to the Earl of Ellesmere, and a great proportion of those in the other numerous coal-pits in my neighbourhood. On referring to my day-book, I find that I have attended twenty-seven cases of burns during the last twelve months. The colliers are generally strong healthy men, most of them under forty years of age. The burns from explosions are chiefly situated on the face, neck, arms, hands, abdomen, back, and chest, as these are the parts most exposed to the action of the fire, in consequence of the men (as you are no doubt aware,) pursuing their calling in a state somewhat approaching to nudity. When an explosion takes place, the candles of the colliers are extinguished, and the men have to find their way in the dark to the mouth of the shaft in terror and confusion; hence it happens that the burnt surfaces coming in contact with the sides of the pit, have the cuticle destroyed, broken, or abraded in many places, more especially about the shoulders and fingers.

When I commenced practice I adopted Dr. Kentish's plan of treatment, but the turpentine gave such horrible pain that I was obliged to relinquish its use. If I gave anodynes in doses sufficiently large to allay the pain, they appeared to produce more harm to the system in general than the turpentine appeared to benefit the burns; I therefore speedily abandoned the use of the spirit of turpentine, and of the turpentine liniment, and substituted a cerate composed of equal parts of the Unguentum Resinæ, and Ceratum Cetacei. I have read of cases in which the spirit of turpentine is said to have produced soothing effects, but I never witnessed such a case; on the contrary, in all the cases in which I have seen it used, it produced intolerable pain and suffering. I think that my cases are cured quite as speedily with the use of diluted Unguentum Resinæ as when I used turpentine; but I have an impression that the cure of burns does not depend so much on the remedies employed externally in the first instance, as on the subsequent vigilant watching, careful dressing, and after-treatment. I am satisfied that whoever wishes to gain credit in the treatment of burns, must pay particular attention during the suppurative stage, in order to insure the well-doing of his patient. As soon as I see an adult after a burn, I give him sixty drops of a solution of the acetate of morphia, equivalent to half a grain, and repeat the same every hour, if necessary for the relief of the pain, which generally subsides after one or two doses of the opiate. I consider it advisable to give a large dose of the morphia, having seen the best results from such a practice. As speedily as possible I cover all the burnt surfaces with the cerate above alluded to, spread upon linen, or cotton, and when suppuration is established, instead of continuing the diluted resin ointment, I apply the Pulvis Calaminaris freely to the ulcerated surface, and cover it with the Ceratum Calaminaris spread upon linen or cotton as before. I dress my patients daily, and administer internally salines and opiates throughout the treatment, and castor oil as an aperient. The following case will better explain my mode of treatment:—

Case.—Isaac Jones, aged 22, a collier, on the 11th of May, 1847, received severe burns on the whole body above the loins, his hands being very much bruised in finding his way to the mouth of the shaft. I immediately gave him sixty drops of the solution of morphia, (half a grain,) and dressed his burns with the resin cerate, which was continued till the 17th, being six days since the receipt of his injuries. Suppuration in the mean time having been fully established, and the cuticle detached along with particles of coal and dust, I prescribed the application of the Pulvis Calaminaris over the whole surface of the burns, over which the Ceratum Calaminaris was applied. These dressings were continued daily, in combination with a strong solution of the sulphate of copper, until the 29th, on which day the sores were healed, without the slightest deformity. The internal medicines were opiates, salines, and castor oil.

In the case I have just related the discharge of pus was excessive, particularly from the back, and probably increased by the hot weather and a close apartment. Burns situated on the back are very troublesome and difficult to treat. The patient should be raised into a sitting posture at the time he is being dressed, with his arms crossed or extended before him, and the entire discharge should be removed, and all the moisture allowed to evaporate, before the dressings are applied to the granulating surface: many days are gained in the treatment by adopting this method. I have the highest opinion of the Pulvis Calaminaris as an absorbent in the treatment of burns. I formerly used the Creta præparata but it did not answer anything like so well. The timely use of the calamine powder and the solution of the sulphate of copper, will facilitate in a surprising manner the healing of burns arising from the causes mentioned above.

Subjoined is a table of twenty-seven cases which have been treated by me within the last twelve months, on the plan above detailed. Of the two deaths which took place, one occurred on the second day, before re-action was established, and the other sank on the eighteenth day from a sudden attack of diarrhœa. In those which recovered, there were no marks or deformities.

Name.	*Age.*	*Parts burned.*	*Result.*	*Days under Treatment.*

From F. A. Bulley, Esq., F.R.C.S., Surgeon to the Royal Berkshire Hospital, Reading.

Mr. Bulley has forwarded to me a reprint of a paper which appeared originally in the *Medical Times*. In the note accompanying it he remarks "Having experimented largely on the use of the treacle bath, diluted and undiluted, I have ascertained that the effects of each way of using it are quite different, and that those effects which I have detailed in the paper are not procurable by the use of the treacle *alone*, as used by Mr. Greenhow and others. It is all important that the mixture should be applied at the temperature* of the body, to prevent the danger of metastasis, which so often follows cold applications. The remedy, as I use it, is not intended to exclude the air, for which purpose the treacle alone was suggested, but for the purpose which I have more fully detailed in the paper."—S.C.

There are no accidents to which the human frame is liable, the treatment of which has been so various or undeterminate, as that of injuries by fire. In one class of cases it has been recommended that stimulating applications should be used; in another, that they should be of a sedative nature; while in many cases

* There can be no doubt that Mr. Bulley is quite right in attaching importance to *temperature*. It has not been remarked (as far as I know,) by any observer, that most of the popular remedies in burns are either *non-conductors* of heat or *calorifacients*. Cotton, flour, resins, &c., are non-conductors; turpentine and the essential oils are calorifacients. I am trying to establish by experiment this view. If successful, it appears to me that a great stride will have been made towards reconciling the conflicting statements in books respecting the efficacy of different remedies in burns. It would, of course, likewise upset the popular opinion that all remedies for burns act only by excluding atmospheric air.—S. C.

the exclusion of the air from the burnt surface has been supposed to be of the first importance; but, whatever may have been the means suggested for their relief, they do not appear to have been formed upon any fixed principle, and every medical practitioner must at times have found a difficulty in determining which of the many different methods would be the best to be adopted in an emergency of this kind.

I shall, therefore, be excused for relating a few cases illustrative of a simple mode of treatment which, as far as I am capable of judging, is applicable to burns of every degree of intensity, and which I have been in the habit of employing for several years past, both in hospital and private practice, with the most satisfactory results.

The remedy in question consists in the application of treacle and water, in the proportion of one part of the former to three of the latter, over the burnt surfaces, at a temperature of 98°, by means of lint soaked in the solution and laid over the whole of the injured parts. This dressing is to be changed night and morning, the lint having been kept moist during the day by occasional saturation with the mixture of the same temperature, most readily done by soaking a sponge in the fluid, and at intervals squeezing its contents over the lint while still in contact with the surface. The constitutional means to be adopted will be best understood from a perusal of the accompanying cases :—

Case I.—Martha H——, aged 16, was admitted into the Royal Berkshire Hospital, October 7th, 1846, on account of a burn which she had received by the explosion of a box of gunpowder, that had been left in a cupboard, to which she had inadvertently gone with a lighted candle. Half an hour had elapsed since the occurrence of the accident before I saw her, when the following appearances of injury presented themselves :—Her face, which was of a much darker colour than natural, and enormously puffed and swelled, was in the most agonizing pain, and it would have been impossible for her most intimate friend to have recognized a single feature, so great was the disfigurement of her countenance. Her eyes were deeply sunk in the surrounding swelling, with great puffing of the lids, so that it was impossible by any means to ascertain whether the eyeballs had been injured or not by the fire. The whole skin of the face and eyelids was in a state of active inflammation, which appeared to have been increasing during the short time which had elapsed since the occurrence of the accident; the forehead, and at least one half of the hairy scalp, were in the same swelled and puffy state, the hair having been burnt off close to the skin. On the fore part of the neck the injury extended from just below the angle of the jaw on the left side, downwards towards the left breast, and in a large portion of this burnt surface the skin and subjacent cellular tissue were destroyed, the former having assumed the dark brown hue indicative of its complete disorganization. Both arms, from the shoulders downwards, and in the whole circumferance of the limbs, were burnt in the same degree as the face, but without abrasion of the surface; the whole of the integuments, with the exception of a patch on the upper part of the arm, near the left shoulder, which had been more deeply injured, being in the same reddened, swelled, and violently inflamed state. The skin of the hands and fingers had been completely rubbed off, owing to her having hastily laid hold of the handle of a pump, in her endeavour to get some water to assuage the pain. There were several large and deep burns over the fore part of the chest, where the skin and cellular membrane had been entirely destroyed.

The treatment immediately adopted was the application of lint, saturated with the mixture of treacle and water warmed, over the whole of the injured surface, with the exception of the hands, which were carefully dressed with simple cerate, to prevent adhesion of the raw surfaces between the fingers. The direct effect of the application was a slight increase of the pain, which lasted for a few minutes, and then subsided, leaving her comparatively free from the intense and burning heat from which she had just previously been suffering. After the first day or two she felt no pain on the application, but only its soothing effect, which every day became more and more apparent. Sometimes the dressing, though not painful, was very fatiguing, so that it was necessary to give her a little wine, which was more necessary when the extensive surfaces began to discharge pus.

Altogether, the treacle dressing was employed for six weeks, using it morning and evening in the same manner as when first applied. For the first fortnight she was much troubled with a feverish thirst, which left her, however, at the end of that period; but she never had any particular rigors, nor, with the exception of occasional slight pains in the chest, any such internal uneasiness as would indicate a disposition to metastatic inflammation of any kind.

At the end of six weeks the inflammation, which had more or less affected the whole of the injured parts, had nearly subsided, and the skin of the arms, after having been covered with a purulent incrustation, which had once or twice exfoliated and reappeared, had assumed in a great measure its natural appearance, with the exception that in the upper parts, where it had been more deeply burnt, the hollows formed by the loss of the integument and cellular tissue still exposed a large granulating surface, but perfectly smooth and level.

The skin of the face and head had undergone the same change as that of the arms, having become covered once or twice with the same kind of purulent crust, which had afterwards exfoliated, leaving the cuticle smooth and unaltered, with the exception of its having assumed a brownish colour, which remained for some time after her discharge.

After this period, viz., six weeks from the date of the accident, simple cerate was applied to the granulating surfaces, the carbonized skin having become wholly exfoliated, and the treacle dressing was used only to the surrounding sound integument, with a view to soften it, and give it an additional extensibility, and allow of its being drawn more evenly towards the centre of the wounds in the progress of healing, which in some cases it seems capable of effecting, and to which in some measure I attribute the smoothness of the cicatrices, and the absence of puckering in the

neighbouring integument, which I have reason to believe is occasionally obtained by this mode of treatment.

The cure was, as is usual in such cases, somewhat tedious and protracted; but on her discharge from the hospital, at the end of four months and a half, all the wounds had healed, and, notwithstanding the original amount of injury (considerably more than a fifth part of the body having suffered from its effects,) little or no contraction was perceptible at any part—a result, from the apparently hopeless nature of the accident, at first scarcely to be anticipated. The internal remedies had consisted of small doses of syrup of poppies, frequently repeated, with, as circumstances required, more powerful opiates; also occasional doses of castor oil, as the most unirritating aperient, and as least calculated to favour the occurrence of metastatic intestinal irritation, which saline and drastic purgatives would appear in some cases to do. It is a remarkable circumstance that, during the whole period of treatment, there was an entire absence of any odour of putrescence, as accompanying the putrefactive decomposition which usually follows the destruction of living parts by fire.

Case II.—Alice A——, aged 9 years, admitted Dec. 8th, 1846. She had been left by her mother, with another child, while she went to work, in a room with a fire, when by some accident her clothes ignited, occasioning a burn, which on her admission was found to occupy the greater part of the upper arm, the axilla, and a considerable portion of the back part of the body on the left side. On these parts the skin had been completely destroyed, but in other parts, as in the forearm of the same side, the injury had not been so severe, the integument not being actually disorganized, although intensely reddened and inflamed by the action of the fire. On the hand there were several large vesications filled with a transparent fluid, which had collected before I saw her. She suffered intense pain, especially in the inflamed portion of the skin of the fore-arm and hand, where it had not been destroyed; the parts that were actually destroyed were, as is usual, not so painful. Lint soaked in the warm mixture of treacle and water was applied over the whole of the injured surface, with the effect of almost immediately relieving the pain, and appearing to put a stop to any further extension of the inflammation beyond what had been originally occasioned by the burn. The internal treatment was precisely the same as in the last case, with the exception that no other opiate was necessary besides the syrup of poppies, and that she took small doses of castor oil more frequently.

The effect of the external application in this instance, appeared to be, as in other similar cases, slightly stimulating at first, but afterwards of a decidedly sedative character. It also seemed to possess the power of checking or preventing the putrefactive decomposition which often takes place in these cases, rendering the patient very offensive to the other inmates of the hospital; for instead of softening and sloughing, and coming away in putrefied masses with the dressing, as it usually does, the skin became hard, black, and shrivelled, gradually separating from the surface of the granulations at the margin by a kind of exfoliation, until at the end of a fortnight the whole of it had been removed. She was discharged March 23rd, 1847, the wound in the axilla not having completely healed, with a very slight disposition to contraction, which, owing to the peculiar situation of the burnt wound, although it seemed to moderate it a little, the remedy was not altogether capable of preventing.

Case III.—Charlotte L——, aged 6 years, admitted December 31st, 1846. From the same cause as in the last case, her clothes had caught fire, occasioning a burn, which occupied a large space on the upper part of the back, on the left side, extending into the axilla and for some distance down the upper arm. Over the whole of the burnt surface the skin had been destroyed, as well as the cellular membrane underneath, and had the soft quaggy feel of complete disorganization. There was no difference in the intensity of the burn in any part, the integument having been destroyed wherever it had been touched by the fire. Owing to the complete destruction of the parts, she did not seem to suffer any considerable pain, but, as she had only partially recovered from a protracted typhus fever, was a very unfavourable subject for so severe an accident. She had a feverish appearance, and complained of some slight pain in the bowels, but had no rigors. The same external remedy was applied as in the last case, but with a larger proportion of treacle, as the parts were not particularly painful. Internally she took syrup of poppies two or three times daily, with occasional doses of castor oil. At the end of a fortnight the whole of the destroyed integument had separated from the granulating surface underneath, having become previously converted into a dry and dark brown substance, which was removed as it became separated at its edges, by cutting it off with scissors, to allow of the application of the cerate dressing to the granulations, when the treacle could no longer be of service. The denuded surface suppurated freely, so that, as well as from her previously enfeebled condition, it was found necessary to support her strength by giving her port wine and tonic medicines; but at the date of her discharge, March 23rd, 1847, the wounds had nearly healed, and as far as I could judge, notwithstanding their unfavourable situation, with but little danger of contraction. She had also recovered from the debilitating effects of the fever, from which she had suffered prior to the accident.

The foregoing cases are only a few of those which have been treated under my observation, in the manner I have detailed; many have been slighter instances of injury, and several as, or more, severe; but in all of them the beneficial effects of the remedy were more or less perceptible. Of course in some, the parts had been so extensively destroyed that there was from the first no prospect of recovery; but even under these untoward circumstances, I have fancied that the simple means I have employed have lightened the patient's sufferings and prolonged the fatal termination.

The action of the remedy appears to be *directly sedative*, and, as far as I have been able to observe, its first effects have been to lull the pain and moderate the

inflammation which almost always exists in the integument surrounding parts which have been recently destroyed by fire, and which has a tendency to a destructive progress if no effective means are used to prevent it. That this also applies to deeper-seated tissues, and is a frequent cause of the fatal termination of such cases, is substantiated by the observation of Mr. S. Cooper, who, in reference to this subject, remarks:—"The extent of the mischief is often difficult to judge of directly after the accident, notwithstanding the characters of the various degrees of organic injury are strongly marked: for at the same time that the heat disorganizes the parts on which it acts with the greatest violence, it always affects the textures immediately below them; and, though they may not be killed *in the first instance*, they may not be capable of bearing the subsequent inflammation, and afterwards mortify." Whether the remedy is capable of exercising the same beneficial influence upon these deeper seated-tissues, as it appears to do on the more superficial ones, I cannot for certain say, for, until the separation of the skin, they are not exposed to view; but, to the best of my judgment, it does so, moderating the inflammation here in the same manner as it does in the integument.

Its next most obvious effect appears to be that of modifying the tendency to putrefactive decomposition, which destroyed parts are prone to undergo prior to their separation as sloughs; and that it is capable of exercising such an influence I have scarcely any doubt, having had repeated opportunities of observing it, especially in the cases I have related, where its action in this respect was very remarkable, as the slightest putrescent or unpleasant odour could not be perceived during the whole period of the treatment. I had an excellent opportunity of observing this latter circumstance in a case which, through the liberality of one of my colleagues, was placed under my hands for treatment. Although no less than 270 superficial inches of integument (principally of that covering the abdomen,) had been destroyed, I could not, nor could those more immediately about the patient, at any time observe any particular smell. I may mention that this patient lived a month, and at the time of her death, the whole of the integument having undergone the carbonizing changes observed in similar cases, had separated from the surface, which had begun to suppurate freely. On dissection there was no evidence of the duodenum or any other part of the intestines having been inflamed by metastasis, but she appeared to have sunk from the great suffering she had undergone, as well as from the shock, from which she had never completely recovered. There was a slight turgescence of the posterior part of the right lung, but whether from subsidence or other cause could not be accurately determined.

It remains only to endeavour to account for the smooth and regular cicatrization, which I have reason to believe is assisted by this method of treatment. It occurs, I think, in this way:—The disorganized integument and cellular tissue, having undergone carbonization, remains adherent to the parts beneath, and while it is so in contact acts as an extraneous substance by excluding the air, from the surface, and mechanically represses the growth of what would otherwise be exuberant granulations. As the carbonized integument is first observed to separate from the margins, the granulations round the periphery of the wound, by the contracting process which Dupuytren ascribes to the approximation of the margins to the central point, begin to cicatrize before the centre of the wound has become uncovered, which always happens last, and thus a gradual and even cicatrization follows.

It will also be observed, that what would otherwise be called the separation of a slough is prolonged by this treatment, until the system has recovered strength to furnish healthy granulations, in contradistinction to those irregular and unhealthy masses which are produced on a too early separation of the sloughs, in a constitution yet suffering from shock, and aided in many cases by the stimulating applications which are sometimes employed. Perhaps, also, the constant application of the treacle dressing to the neighbouring skin, by rendering it more supple and extensible, may favour a more regular cicatrization, by enabling it more evenly to be drawn towards the margins of the cicatrizing wounds.

From John Higginbottom, Esq., Surgeon, Nottingham.

Since my communication in the *Provincial Medical and Surgical Journal* of the 28th of February last, it occurred to me that I should have added the following remarks:—

After the application of the nitrate of silver to a sore or ulcer, its action continues for three or four days, during which period its antiseptic properties are very apparent, for there is not the least fœtor, as it quite prevents the putrefactive process. This is a valuable property of the nitrate of silver which I have omitted to mention, although I have observed this result in my practice for many years.

I thought it might be as well to give *once more* the proportions of the concentrated solution of the nitrate of silver, which is as follows:—Eight scruples of nitrate of silver, twelve drops of nitric acid, and eight drachms of distilled water. I prefer this strong solution to a weaker one, as it can be readily and safely applied, either very slightly, or in a more severe degree, as surgical cases may require. In burns and scalds, one slight application on the inflamed surface, and two upon the denuded surface, I have found sufficient.

From Charles Clough, Esq., Surgeon, Southport.

My views on the subject of burns are, that cases of this kind are to be treated in a great measure as other inflammatory affections. In extensive burns, and especially in deep burns or scalds, it has always been my practice to apply for two or three days stimulant dressings,* to excite or promote the circulation through parts, the action of whose vessels you would suppose was weakened; but after this has been effected, common dressings, and the

* In the first instance, in severe burns, I apply both the Oleum Terebinthinæ, and the Linimentum Terebinthinæ, and continue the latter three days.

attention required for other sores, are wanted in these. To exclude the atmospheric air and prevent evaporation, seem to be the principal objects. Linseed oil and lime water has always appeared to me a cheap and very convenient application to fulfil the indications required. I should have almost the same objections to apply cold in extensive or deep burns, as I should have to apply heat to a frost-bitten part.

Foreign Department.

ON THE EMPLOYMENT OF LARGE DOSES OF TARTAR EMETIC IN THE TREATMENT OF PNEUMONIA, ESPECIALLY IN CHILDREN.

By Dr. Herard.

Dr. Herard observes, that although it is now universally allowed, that doses of tartar emetic, which toxicologists heretofore pronounced poisonous, may be administered with safety, yet the greatest discrepancy of opinion prevails as to the amount of benefit derivable from these, notwithstanding the question has received so much illustration from very able writers. Having had the opportunity of witnessing the treatment of pneumonia by tartar emetic at the Hôtel Dieu, by M. Sandras, and at the Hôspice des Enfans, by MM. Baudelocque and Blache, and this in a great number of cases, he believes that the results may be advantageously published, especially as the antimony was the only remedy employed. He does not agree with those who consider that because we have so powerful a therapeutical agent as bleeding, enquiries like these are superfluous; for not only is it desirable to possess more than one efficacious means, especially if their conjoined use is found to diminish the chance of death, and hasten convalescence, but there are cases in which bleeding cannot be performed without danger, as in ataxic pneumonia, particularly that of drunkards, and in pneumonia which manifests itself in persons already exhausted by prior diseases, or by being surrounded with anti-hygienic circumstances. Children, too, at least those who are found in hospitals, ill bear blood-letting, even in its mildest form.

Dose, and Mode of Administration.—In the adult the dose has been rapidly raised from five or six to ten grains, but never carried beyond this; while in children, commencing with one grain and a half or two grains, it has rarely reached five grains. It has always been administered in a julep, giving a spoonful or two every hour or every second hour, suspending it for two or three hours after meals, and preventing the patient drinking too much of ptisans while taking it. With such precautions the medicine becomes easily tolerated, the great error of practitioners being the administering it in too large a quantity of fluid. Moreover, a small proportion of syrup of poppies or gummy extract of opium is always added to the julep.

Action on the Economy.—1. *On the Alimentary Canal.*—The author's investigations in no wise confirm the assertions of those who state that inflammation of the bucco-pharyngeal mucous membrane is a common result of the employment of large doses of antimony. In four or five cases only out of sixty in which these were given did he meet with a slight aphthous ulceration, apparently resulting from the child's retaining the julep in the mouth before swallowing it. In seven only of thirty-one infants did the tartar emetic produce repeated vomiting and purging; in twelve the tolerance became established by the second day; while in the rest these symptoms were absent from the beginning. As a general rule, tolerance is more rapidly and durably established as regards the stomach than the intestines. Diarrhœa is, however, seldom increased by the antimony, and in some cases obstinate constipation follows its use. When tolerance is of somewhat difficult establishment, it seems to be more readily brought about by increasing the dose, and the frequency of administration, than by a contrary proceeding. After the fever has subsided, and the medicine is only continued because of the persistence of some local symptom, tolerance is still maintained. Some patients even take it at their meals, and in others it seems to excite the appetite.

2. *Circulation.*—All observers agree that antimony exerts a marked effect in diminishing the number of the pulse. This, in the adult, rapidly falls from 105 to 80, 70, 60, or even 45. In the child the diminution is less marked and less permanent, the pulse still retaining somewhat of the oscillatory character proper to the time of life. This effect upon the pulse cannot be said to result simply from the ameliorated state of the patient, since it is observed the very next day after giving the antimony, and during the existence of very grave pulmonic lesions, ascertainable by the stethoscope. More than once a pulse, which had descended to 50, has risen to 70 on discontinuing the antimony, again to fall on its resumption. This effect upon the pulse is usually more marked in proportion to the ease with which tolerance is established. Simultaneously with the diminution of the number of the pulse, there is sometimes, but not always, an enfeeblement of the arterial and cardiac pulsations; but the intermissions and irregularities mentioned by Trousseau have not been observed by the author. The effect upon the pulse is sometimes long in disappearing, this continuing slow for several days after the suspension of the medicine.

3. *Respiration.*—This, as well as the pulse, has almost always been found slower than natural, but its condition is much more difficult of exact appreciation, especially in the child. It is best examined during sleep, and then is found sometimes to have become affected even by the second dose.

4. *Secretions.*—Transpiration has not seemed either in the adult or child to be increased by large doses of antimony; nor has the increased secretion of the urine, noted by some authors, been observed.

Mode of Action.—Many excellent observers explain the curative agency of antimony in pneumonia by the powerful sensation it produces upon the alimentary canal; and M. Chomel attributes some of the advantage to the mechanical effect which the repeated vomitings exert in disgorging the lungs. But if these explanations are correct, the medicine should be given in smaller doses, for these exert a far more powerful

effect upon the alimentary canal than the larger ones; and every emetico-cathartic medicine might be expected to operate beneficially. In fact, the most marked benefit is derived from the use of antimony, just in those cases in which its complete toleration prevents any effect being produced upon the stomach or intestines. According to others, it determines towards the skin the morbid material which had become concentrated upon the internal organs; but the slight amount of increased transpiration ill accords with this explanation.

The rapid and marked depression of the circulation and respiration has been differently explained. Some, as Mialhe, have seen in it a chemical action, by which the oxidizing power of the lungs upon the blood becomes diminished; while others, as Trousseau, believe that the antimony admitted into the circulation acts directly through the nervous system upon the heart and inspiratory muscles. The lung consequently receives in a given time, a less quantity of blood, and has, as an instrument of hæmatosis, less blood to elaborate; and it is to this repose of the diseased organ that we may refer the resolution of the disease. To this it may be objected, that antimony is as efficacious in some other inflammations, as rheumatism. The author of the present paper is not disposed to add to these hypotheses, but observes that, however explained, the diminution of the number of the pulse is, in some measure, the index of the beneficial effect of the remedy. When this is marked and rapid, a cure is almost certain.

Therapeutical Effects.—The antimony, in the present series of observations, was administered to nine adults and thirty-one children. Of the former, one patient, admitted in an advanced stage of the disease, died; and the rest were completely cured. Of the children, seven died; two falling victims to tubercular pneumonia. In the other five, lobular pneumonia was very extensive; and five in thirty-one is a very favourable proportion in a disease so fatal as is the pneumonia of young children in a hospital. Lobular pneumonia is far less amenable to tartar emetic than the lobar; and those cases of broncho-pneumonia, as M. Guersent terms them, occurring in children under two years of age, are generally far more efficaciously treated by emetics than by antimony given in contra-stimulant doses. For the same reason, probably, the Rasorian method is less successful in aged persons than in the adult; for it is well known that at this period of life, pneumonia is complicated with bronchitis, and the characteristic tubular *souffle* is often absent.

So, also, in pneumonia succeeding to bronchitis, M. Sandras has found antimony far less efficacious than in cases of pure pneumonia. The most remarkable fact among the present cases was the rapid disappearance of the bronchial *souffle*, and its replacement by crepitant or sub-crepitant rales. Bleeding itself does not produce so rapid a passage from the second to the first stage of the disease. Frequently on the day of commencing the antimony, bronchial respiration, with bronchophony and resonance of the cough over the half of a lung, were ascertained, and the next day *râles*, more or less fine, might be heard over this entire space. Had this phenomenon been met with only once or twice, we should have explained it by the undoubted changeableness of the stethoscopic signs in childhood; but the result was obtained in so many children, that it would have been impossible not to refer it to the antimony, if even it had not been equally exhibited in the adult. The crepitant *râle*, on the other hand, persists with remarkable tenacity, and, becoming assimilated in character to the large, moist, sub-crepitant *râles* of chronic or subacute bronchitis, may extend far into convalescence, every other sign of returning health being present. The rapidity with which convalescence takes place, is, indeed, one of the most remarkable and advantageous results of the use of antimony. It can hardly be said to exist, so rapidly does health return, giving this method of treatment an infinite advantage over blood-letting in this respect.

Notwithstanding his conviction of its great efficacy, the author would not recommend tartar emetic as an exclusive remedy, believing, as a general rule, that the disease in adults is most advantageously treated by combining the antimony with venesection. It enables us to do with fewer blood-lettings, while these favour its absorption. But, to render it of service, practitioners must be convinced of its therapeutical importance, and prescribe it from the commencement, not as a mere accessory, but as an heroic remedy. In children *above two years of age*, it should be regarded almost as an exclusive medication, although in exceptional cases one or two emissions of blood or a blister may be required; this last, sometimes, however, often proves a dangerous remedy in hospitals.—*L'Union Médicale*, Nos. 127 to 131.

NOTES FROM A PRACTITIONER'S DAY BOOK.*

INTESTINAL IRRITATION A CAUSE OF ASCITES.

Irritation of the mucous membrane of the intestine will, under certain circumstances, cause an effusion of fluid into the peritoneal cavity. I once examined the child of a physician, a little boy about eleven years of age, who gradually emaciated and died from a chronic disease of the abdomen, with frequent diarrhœa, remaining after an attack of fever about two years before. At one time during this interval there had been considerable ascites, but it subsided under a diuretic treatment, and when the autopsy was performed, no fluid existed. Every abdominal and other organ was found in a perfectly healthy condition, with the exception of the jejunum and ileum, which exhibited several chronic ulcers of the mucous membrane, and three or four of the neighbouring mesenteric glands, which were enlarged from irritation. The peritoneum, even where it was contiguous to these lesions, showed no thickening nor other trace of its having been the seat of inflammatory action.

A nervous hysterical young lady had an attack of common autumnal diarrhœa which was then very prevalent. Before this had completely subsided, an extremely tympanitic state of the abdomen supervened, and in the course of a few days, the lower part of the distension was ascertained to consist of an effusion of fluid

* Continued from page 667 of last Volume.

into the peritoneal cavity, being readily removed by a few doses of a diuretic medicine.

A POINT IN THE TREATMENT OF MAMMARY ABSCESSES.

The following is a case of no very unusual occurrence :—A mother loses her infant, and, broken-hearted at the event, she neglects to pay that attention to herself which her case requires. No attempts being made to relieve the distended breast of its secretion, the gland becomes hard and painful. and at length abscesses form in different situations. If the treatment is confined to the evacuation of matter by puncture, and to the application of fomentations and poultices but little good is done. The former abscesses continue to discharge; fresh ones are constantly forming, and the woman at length sinks into a state of hectic. Means should be used to stop the secretion of milk, which has been going on all this time, and perpetuating the mischief. We have no better means of effecting this than by the administration of a hydrogogue purgative. I am usually in the habit of prescribing the sulphate of magnesia in the compound infusion of roses, to which, when there is much hectic and debility, I add some quinine, and dilute sulphuric acid. The effect of this treatment is sometimes almost magical. I have known a woman, who for months had been suffering from a succession of mammary abscesses, begin to get well from the moment that the salts produced its liquid evacuations from the bowels; the secretion of milk ceased, and the purulent discharge diminished, a more adhesive inflammation being established in the place of these two actions.

APHONIA CURABLE BY INHALATION OF THE FUMES OF BENZOIN.

A middle-aged spinster lady, consulted me about her voice, which she had lost for more than twelve years, having never, she assured me, during the whole of this long period, been able to do more than speak in a whisper. There was no cough, and a most careful examination with the hand and stethoscope led me to conclude that there was no organic or inflammatory change in the larynx. She was a nervous excitable creature, and I could only consider the case as one of hysterical disinclination to use the muscles which make tense and approximate the chordæ vocales. I had no reason to expect any benefit from treatment, and was quite at a loss what to prescribe. On my table there happened to be lying a packet of fumigating cards, made by impregnating blotting paper with benzoin and nitre. In my dilemma these met my eye, and snatching up the box I gave her a few, directing that one should be burnt every night, and its fumes inhaled. In a week or ten days she came again, and said she thought she was better, as her voice had risen to a squeak on one occasion. I urged a most persevering continuance of the remedy. Four months afterwards, happening to be in her neighbourhood, I encountered her, and to my great surprise she addressed me in a laryngeal tone, not yet very sweet indeed, but in a good serviceable voice, though a little rough. It was not capable of anything like modulation, but grated along at a uniform pitch, never apparently rising into a squeak, nor falling off into a whisper. During the whole four months she had most unremittingly used the fumigating paper, with the exception of a few days when she was suffering from a cold and cough. The improvement at first consisted only in an occasional grunt whilst talking, and during the last fortnight her voice had resumed a uniform laryngeal tone, which had been gradually becoming stronger.

The fumigating cards are made in this manner :—A sheet of thick white blotting paper is brushed over with a saturated solution of nitre until it is thoroughly wet, and when dry the compound tincture of benzoin is applied in the same manner. Each of these applications is repeated more than once if necessary. When thoroughly dry the paper is cut into slips, three inches long, by one and a quarter wide. One of these being lighted at the corner, burns without flame like tinder, emitting a dense white smoke, consisting principally of benzoin acid and some particles of nitre, which are thrown off by the crepitation of the crystals. When used for remedial purposes, this smoke should be inhaled by holding the head over the burning card.

A young woman suffered from a common catarrhal sore-throat, which lasted rather longer than usual. About a fortnight afterwards I was consulted, and found all the acute symptoms had subsided. She now merely experienced a defect in the power of speaking in a laryngeal voice, and all her words were uttered in a whisper. I recommended her every night inhaling the smoke of a fumigating paper. The very morning after the first time of doing so a great improvement had taken place, whilst by a few days' continuance of the treatment she was enabled to speak in a natural tone.

(*To be continued.*)

General Retrospect.

ANATOMY.

REMARKABLE ANOMALY OF THE AORTA.

The following particulars are derived from a *post-mortem* examination by M. Bouillaud.

The aorta for its whole length was divided by a septum, commencing immediately above the free border of the semilunar valves, and extending to the common iliacs. One of the semilunar valves was common to the orifices; the other two belonged each to a single orifice exclusively.

In the descending portion of the aorta, the wall of separation was perforated by small holes, most numerous at its lower part, and at its very end, just above the primitive iliacs was an opening much larger than any of the foregoing, (nearly two-fifths of an inch in diameter,) which very much resembled the foramen ovale, being oval and bordered by a kind of thin valve.

The left division of the aorta gave off the innominata, left primitive carotid, intercostal, lumbar, cœliac, and superior and inferior mesenteric arteries.

The left sub-clavian arose from both divisions, and was divided like the aorta in the first part of its course, but the rest of the artery not having been preserved, it is not known what disposition it presented.

One coronary and one renal artery came from the right division, and their fellow arteries from the left.

In the right division, at points corresponding to the

origin of the innominata, left carotid, cœliac axis, and mesenteric arteries, were cul-de-sacs lying alongside of those vessels where they sprang from the aorta. The smaller division was dilated at its orifice, and in its transverse portion to a circumference of about three inches and a half. The larger division, immediately above its origin, was dilated to about the size of a turkey's egg. The three coats of the artery were here distinguishable, if anything rather thicker than in the normal state. In its transverse portion, (at the commencement of which it suddenly contracted,) it became enlarged to the size of a small hen's egg, the seat of the latter dilatation corresponding to that of the second dilatation of the smaller division.

The right division, for its whole extent, exhibited calcareous degeneration and roughness of its internal surface. In the left were some unevenness—fibrous, or fibro-cartilaginous, but no calcareous formation.

The internal circumference of the larger division of the aorta was from two inches and 2-5ths to two inches and 3-4ths; two inches and 3-4ths in its descending portion, and two inches and 2-3rds above. That of the smaller division was about two inches at the origin of the innominata, from one inch and 3-5ths to one inch and 3-4ths in its descending thoracic, and from one inch and 1-5th to one inch and 3-5ths in its abdominal portion.

There was general and very great hypertrophy of the heart; in the pericardium were some opaque spots, but in neither it nor in the heart was there any calcareous deposit.—*Southern Medical and Surgical Journal*, Nov. 1847.

PATHOLOGY & PRACTICAL MEDICINE.

OBLITERATION OF THE SPERMATIC DUCTS.

M. Gosselin shews that the ducts destined for the passage of the seminal fluid are liable to become obliterated, just as the ducts for the transmission of bile, saliva, &c. The points at which he has observed obliterations are:—1. The vas deferens; 2, the globus minor of the epididymis; 3, the globus major of the same body; 4, the seminiferous tubes. He supposes these changes to be not an infrequent cause of impotence.—*Archives Générales.*

CANCER OF THE UTERUS SIMULATED BY THE IRRITATION OF A PIECE OF SPONGE.

Dr. Mitchell relates the following instructive case:—Mrs. P., aged 26, a delicate anæmic woman, married two years; commenced menstruating at sixteen, and has been regular up to the last year and a half. When four months married, she had an abortion, and amongst other means employed to arrest the flooding the vagina was plugged. She continued for a long time in a very precarious state, and has never been well since. She now (January 16, 1846,) complains of great pain at the lower part of the abdomen, with constant pruritus of the vulva; but what distresses her most is the constant discharge of a dirty sanious fluid from the vagina, varying in quantity at times, but always increased during the menstrual period, the fœtor being at all times unbearable. She has consulted several medical men, some of whom have pronounced it cancer. She is much emaciated, and in very low spirits, having tried a variety of remedies without benefit. The speculum has been used, and applications made to the part. On examining with the finger, the mouth of the uterus could not be detected at all, but a soft fleshy mass, occupying its place, and projecting over the cervix and into the vagina, quite insensible to the touch, could be felt. On introducing the speculum, a dark-coloured fimbriated body was brought into view. The end of an uterine sound was applied to it for the purpose of tracing its attachments, during which examination a small piece was detached. This piece was put under water, and found to consist of a minute portion of sponge, with a quantity of what appeared to be lacerated muscular fibre.

The after part of the treatment was very simple. Portion after portion of the mass was detached without much trouble, the whole being in a completely decomposed state, and only held together by the granulations from the uterus, which were very long and tender. The separation was attended with a small loss of blood. The pieces when put together weighed five drachms and a half. The vagina was syringed out frequently with warm water, and the surface to which the sponge had been applied touched three times with nitrate of silver at an interval of four days between each application. At the end of a month the os uteri was quite normal, with the exception of a slight induration and puckering of the lips. The menstrual function has been naturally performed, and she is gaining strength and flesh. This lady continued to improve, proved pregnant in March, 1846, and was safely delivered at the full period.—*Dublin Medical Press*, Dec. 8th, 1847.

ELEPHANTIASIS.

A remarkable case of this, in this country, unusual disease, is narrated by Mr. Southam, of Salford. The patient, an unmarried female, first came under the author's notice in the autumn of 1843. The disease had then existed about twenty years, and commenced when she was in her eighteenth year, on the dorsum of the foot, having been preceded by attacks of deep-seated pain. As the œdema extended, the pain became more severe, and the integuments the seat of frequent erysipelatous attacks. A large ulcer formed on the inside of the thigh, and three others near the ankle. The only cause assigned for the disease, was the sudden cessation of catamenia from cold. A drawing of the case, taken in 1845, was exhibited to the Royal Medico-Chirurgical Society; the measurement round the calf of the leg was two feet nine inches; above the knee three feet four inches; and at the upper part of the thigh, including the nates, five feet six inches. Owing to the integuments having yielded unequally, the leg had a somewhat lobulated form; there was neither indentation nor pain on pressure: the sole of the foot was the only part of the limb not implicated. She was able to go about the house, and assist in household duties, until within a few weeks of her death, which took place on the 21st of November, 1846, from an attack of dysentery.

On examining the body, the enlargement was found to have been caused by the deposit of a dense white lardaceous substance, interspersed with fat, in the

subcutaneous cellular tissue. The principal venous trunks were much larger than natural, and when divided transversely, were patulous; their coats were thickened and converted into a fibrous substance, disposed round the vessels in laminæ. All the smaller vessels when divided transversely, resembled arteries filled with coagula. The disease in the veins had not extended beyond the groin; those of the pelvic cavity were sound. The viscera were healthy. Nothing beyond slight hypertrophy of the epidermis and cutis was detected in the skin.

The author remarks, that he has been informed by several medical friends who saw the patient, and who had witnessed elephantiasis as it is met with in the natives of South America and the West Indian Islands, that the tumefaction seldoms attains so great a size as was observed in the case now related. From the appearances found on dissection, it is evident that the disease originated from repeated attacks of subacute or chronic inflammation of the venous capillaries, which caused the pain and febrile symptoms. The author is of opinion, that the immediate cause and pathological changes of elephantiasis bear an intimate relation to those of phlegmasia dolens and the induration of the cellular tissue, in new-born children, the apparent differences depending on the degree of venous obstruction, and on the remote influences which have originated it.—*Medico-Chirurgical Transactions*, vol. xxx.

SURGERY.

CASE OF SUB-MAMMARY ABSCESS DISCHARGED THROUGH THE TRACHEA.

By S. C. Sewell, M.D., &c.

Mme. A. D——, aged 29, ten years married, barren, consulted me early in March, 1840, for a painful affection of one breast, which I treated as a case of irritable breast, by frictions of iodide of potassium ointment, ioduretted solution of iodide of potassium, &c. In three weeks she expressed herself much relieved, and dispensed with further attendance. On the 20th of April, Mr. D—— called on me, and stated, that some uneasiness still remaining, and the breast having increased in size, Mrs. D—— had consulted Dr. ——, who had declared it to be cancer, and advised its removal. I immediately went to see her, and on examining the breast, I found that it was somewhat larger than the other, with fluctuation, indicating matter or other fluid behind the mammary gland. I repudiated the idea of cancer, expressing my conviction that it was a chronic abscess between the ribs and gland, and requesting that further advice might be called to decide the controversy. They suggested Dr. Robertson, who came on the following day and confirmed my diagnosis. Owing to the depth of the abscess, we declined making any incision, and the ioduretted frictions were continued. On the 10th of May I was hastily summoned to see Mrs. D——, who, I found, had commenced about an hour before to expectorate pus in considerable quantities; the expectoration was now less abundant; every few minutes a tracheal rale was heard, followed by cough and expectoration of pus. The breast was now the size of the other, and the gland moved loosely under the hand, as though detached. Pressure on the breast caused increased expectoration of matter. I applied a compress and bandage over the breast; the expectoration gradually ceased in four or five days, and Mrs. D—— has remained in good health to the present time. In this case, adhesion of the pleuræ, and perforation of the intercostal muscle, pleuræ and substance of the lung, until a large bronchus was reached, must have taken place. I should have mentioned that there was no effusion of pus into the pleura or emphysema of the cellular tissue, but there was loud mucous rale *à grosses boules* under the abscess.—*British American Medical Journal.*

IMPACTION OF A SHEEP'S TOOTH IN THE BRONCHUS.

A girl, aged 7, was admitted into the Stockport Infirmary under Mr. Rayner, having swallowed a sheep's tooth which she had in her mouth. She was immediately seized with symptoms of suffocation, which had subsided before admission. She remained free from cough for six days, when she had cough with copious expectoration streaked with blood. A minute examination of her chest led to the discovery that the foreign body was lodged in the right bronchus. Tracheotomy was performed, and the tooth was forcibly expelled by the wound, The use of chloroform was found very beneficial during the operation, as it subdued the violent action of the larynx and adjacent parts, which frequently embarrasses the operator.—*Lancet*, Febr. 26th.

APPLICATION IN BURNS.

The following is recommended as an application in burns by M. Thorel, of Avallon :—

Take of Hydrchloric acid (20 degrees,) 50 grammes.
Sulphate of soda, in powder, 65 grammes.
Dissolve.

The burnt part is to be plunged in the liquid, or the latter applied in lotions and frequently-changed compresses.

This mixture is useful only in burns of the first and second degree; it is inapplicable in the case of eschars. It arrests the inflammation instantly, and prevents the formation of phlyctenæ and blisters, or stops their development and breaking.

TREATMENT OF BLENORRHAGIC OPHTHALMIA.

M. Ricord's treatment is as follows:—The patient is to be kept quiet; the head should be raised, and the eyes completely secured from light; the diet very low. The first thing to be done is to rub the nitrate of silver over the affected surfaces, so as to produce a white film. After cauterization the eyes should be sedulously washed with warm water. The patient should be watched after the first use of the nitrate; it will then be perceived that the secretion is momentarily suspended by it, but when the crust formed by the caustic falls off, the pus re-appears, but is lighter in colour, and sero-sanguineous. So long as little white streaks, the result of cauterization, remain visible, and so long as the secretion is not again purulent, it may be judged that the influence of the nitrate continues, but if the secretion has become again purulent, the cauterization

may be repeated; indeed it can be safely used three times a day. The eye must be repeatedly cleansed during the day, and poppy-head fomentations be constantly applied; poultices are to be eschewed as they favour œdema. Mercurial frictions are injurious at this stage, not so at a later period.

If there be chemosis, this state should, if possible, be removed, while it is merely the result of œdema; when it has become phlegmonous, the conjunctiva is so distended as to be with difficulty seized with the forceps. The excision should be preceded by cauterization, and is to be made with curved scissors and flat forceps. When chemosis has reached the phlegmonous state, it cannot be excised, and is to be scarified. If there be much febrile action blood is to be taken from the arm. Leeches may be placed in the course of the jugular vein, or behind the ears. Mustard pediluvia are to be avoided, as the essential oil is apt to irritate the eyes. Blisters on the nape are advisable on the decline of the disease.—*Abstract of Lecture in the Lancet*, Febr. 12th.

THE INTERRUPTED SETON.

Mr. Lennard communicates a mode of counter-irritation which appears to him to have advantages over the ordinary plans. He calls this the "interrupted seton," and it is made by inserting with a small suture-needle, a number of distinct threads into the diseased part, which threads are subsequently tied together. The advantages supposed to exist are:—

1. The immediate action.

2. The perfect command over the extent of surface counter-irritated.

He recommends it in diseases of the serous membranes in particular.—*Lancet*, January 22nd.

PHARMACY.

NEW METHOD OF PREPARING MERCURIAL OINTMENT.

M. Soubeiran prepares in the first place an amalgam of fifteen grammes of mercury and two grammes of tin. He incorporates this with an equal portion of axunge, either by trituration on a marble plate or in a mortar, and he adds the mixed mass to 1,485 grammes of mercury, and one third of the proportion of axunge prescribed by the Codex. (One part of mercury to ten parts of axunge.) A few hours' trituration suffices for the total extinction of the metal. After the completion of the operation he adds the remaining two thirds of the axunge.

This process presents the very great advantage—that it is of most ready execution. The introduction of a foreign body might perhaps be urged as an objection to its adoption. To this M. Soubeiran replies that he has followed this method for the last ten years with the most perfect success, and has seen patients use enormous quantities of the ointment thus prepared, and continue its application for a long period of time, without experiencing the slightest ill effect from it. It is probable that the tin used in the process serves to diminish the cohesion between the molecules of the mercury. M. Soubeiran was led to this supposition the very first time that he had recourse to the new process. He was then endeavouring to prepare mercurial ointment with mercury which he had previously distilled. All his attempts and efforts to extinguish the mercury proved fruitless; and, after eighteen hours' incessant trituration, he had the mortification to find nearly the whole of the bright metallic mercury at the bottom of the mortar, but on subsequently adding the amalgam of mercury and tin, he succeeded instantly.—*Répertoire de Pharmacie*.

TOXICOLOGY.

POISONING BY THE SESQUICHLORIDE OF ANTIMONY.

Mr. Cooke relates the case of W. H——, aged 41, a pot-man at a public-house, of habits corresponding to his calling, who had been drinking rather more than usual for a week, when he locked himself in his room and swallowed an ounce of the butter or sesquichloride of antimony. He immediately experienced a burning sensation in the mouth and fauces, and very soon became insensible; he remained so for half an hour before he was discovered; he was then taken to a surgeon in the neighbourhood, who used the stomach-pump, and in an hour after he had taken the poison he was brought to the hospital, apparently moribund. This was at 4 p.m., April 23rd, 1847. The surface of the body was cold and clammy; eyes lustreless, with inactive pupils; the pulse was so small that it was only by the most delicate fingering it could be perceived; and the expansion of the chest so very slight that respiration appeared indeed to be suspended. In this condition it was quite hopeless to expect any effort at deglutition. External stimulants, such as the application of the strong Liquor Ammoniæ to the nostrils, tickling the same with a feather, and cold affusion to the head, were applied with marked benefit. The apparently dead was re-animated; in ten minutes he swallowed some tincture of bark, diluted with strong green tea, and this was repeated at short intervals for an hour, during which period he vomited some undigested food three or four times. The heart gradually recovered its nearly suspended action, the pulse became regular, the pallor and coldness of the surface were changed (although very gradually, and after he had been some time between blankets,) to a genial warmth, and the blank meaningless eye began to exhibit some perception. But it was several hours before he recovered the power of speech. The vomiting was slight, and did not continue after the first two hours. He slept during the evening and night, and the green tea was continued at intervals. Towards the morning of the 24th he began to complain of severe pain and burning in the throat and abdomen. He had passed water, but the bowels were not relieved. The tongue and mouth were not affected, but the fauces were considerably inflamed; pulse 78, small, rather hard; tongue dry in the centre; some tenderness over the whole of the abdomen; no sickness. He was ordered farinaceous food, with milk, a dose of castor oil, and a grain of calomel, with a quarter of a grain of opium, every four hours; fomentations to the abdomen. He became restless, and the tenderness increased; the pulse got up to 105, hard, until the oil operated freely, when all the symptoms were relieved. Subsequently he

continued to improve daily; the gums were very slightly touched by the calomel, all tenderness of abdomen ceased, and after taking some bark and acid, and good nourishing food, for a few days, he went out of the hospital on the 3rd of May, quite well.

Remarks.—This case derives its interest principally from its rarity, there being but four cases on record, of poisoning from this substance—one quoted by Orfila, from Borrichius, in which a few strong doses of the sesquichloride of antimony were taken by a naval surgeon, for gout. He was quickly salivated; purged "*par haut et par bas*;" collapsed; pulse imperceptible; dyspnœa; but sensible until he died. The other three cases are to be found in "Taylor's Jurisprudence;" two of them recovered; in both these, the poison was administered by mistake. In the third case, from two to three ounces were taken by a surgeon purposely; he died in ten hours and a half. The treatment is not recorded. The antidote is bark.—*Lancet*, Feb. 26th.

[One of the cases here alluded to occurred in the practice of our associate Mr. Bancks, of Stourbridge, and will be found recorded in the *Provincial Journal* for 1846, p. 611.]

RECOVERY FROM A POISONOUS DOSE OF STRYCHNIA.

The following interesting case is reported by Dr. Thomas Anderson:—

Mr. B. was the subject of severe tic douloureux, for which he was in the habit of taking large doses of muriate of morphia. On the present occasion he went to a druggist for some morphia, and received a powder of a yellowish colour, which was stated to be that substance. He took of this his usual dose, three grains and a half, and remarked at the time, that it had an unusually bitter taste, but it did not occur to him that there was any mistake. Shortly after, however, while walking in the street, he complained of numbness in the back of the legs, but not of sufficient severity to cause him any material uneasiness until some time after, when the sensation suddenly increased, together with a want of power. There was, however, nothing unusual in his appearance at this time, as a friend whom he casually met, laughed at his apprehensions. There was no spasm observed. On reaching home the patient felt better and retired to bed about five hours after the first appearance of the symptoms. Previous to stepping into bed, in order to gain a good night's rest, he took a second dose of the supposed morphia equal to the first. In less than ten minutes after he was seized with a violent tetanic spasm, affecting the legs and respiratory muscles, and had only just time to call out for assistance, before the sensation amounted to absolute suffocation. Spasms followed each other in rapid succession, chiefly affecting the legs, back and respiratory muscles. During the whole period the patient was perfectly conscious, his senses being even exalted. The paroxysms, after continuing some time, began gradually to diminish in violence, and it was hoped that they would pass off, when they suddenly recurred with their original severity. This appeared, however, to be the last effort of the poison, as the symptoms entirely ceased about thirteen hours after taking the first dose. The tic douloureux was found on his recovery, to have entirely ceased, and has not since returned.

On his recovery, the patient sent the residue of the supposed muriate of morphia to Dr. Anderson, who discovered it to be pure medicinal strychnia.—*Monthly Journal* for Febr., 1848.

QUEEN'S COLLEGE, BIRMINGHAM.

At the monthly board of the Council, held on the 5th instant, the Rev. Chancellor Law in the chair, on the motion of the Mayor, seconded by the High Bailiff, the following report was confirmed and adopted:—

Report of Committee appointed to consider the practicability and advantages of founding a College of Arts in connection with the Junior Department of Queen's College, Birmingham.

"Your Committee begs to report that, as Mr. Sands Cox has now, after more than twenty years' persevering talent and indefatigable zeal, completed his system of Medical Collegiate Education; and as the Junior Department of Queen's College has been brought into full operation, and is found likely to succeed in all respects, and has been favoured with much public notice and approval; and as her Majesty's Warrant has been obtained for the admission of your students to Degrees in Arts and Law as well as in Medicine, the time has, your Committee venture to think, fully arrived when the Council of Queen's College may throw open the benefits of the Junior Department of their College to the sons and wards of gentlemen residing in Birmingham and its vicinity, and elsewhere, (especially to the sons of the members of the medical profession,) extending and adapting the system now pursued with reference more immediately to Medicine to the purposes of education generally. With that view your Committee begs to offer the following suggestions and heads of a plan:—

"1.—Students requiring general instruction to be admissible into the Junior Department of Queen's College, after they have completed an elementary school education—say about the age of sixteen.

"2.—During the first year all students to attend the same classes in Latin, Greek, Mathematics, French, German, Drawing, &c.

"3.—Students who are intended for the Medical Profession to receive during their second year's course of study separate instruction in the rudiments of Materia Medica, Chemistry, Botany, and Pharmacy.

"4.—At the commencement of the third year, such of the junior students as are duly qualified, to enter the Senior Department of the College; those who are intended for the profession of Medicine and Surgery being received into Queen's College; those who are intended for the Law, or the Church, or who desire for any purpose Degrees in Arts, to have provided for them a College of Arts.

"5.—This Department of Arts is what we now propose to found: the education to be such, *mutatis mutandis*, as Cambridge and Oxford supply, fitting your students for Degrees in the University of London, the *curriculum* of study being, as at Cambridge and Oxford, for a period of three years. So that our proposed System of General

Edcation will, for such students as enter the Junior Department at sixteen, be completed at the age of twenty-one.

"6.—But your Committee further proposes, that students may if duly qualified, and if their parents and guardians so desire, have the privilege of entering the Senior Department of Arts at once.

"7.—Also, your Committee proposes that students, both of the Senior and Junior Department, may either occupy rooms in College or reside with their parents or guardians, or with private tutors sanctioned by the Council.

"8.—In furtherance of the above plan, your Committee has much pleasure in reporting that three contiguous houses have been secured in the Crescent, which may easily be so arranged as to afford sufficient accommodation for all the present purposes of an extended Junior Department, and also may be made applicable for the reception of about twenty students in the Senior Department of Arts.

"9.—But, considering the vast population of Birmingham and its neighbourhood, your Committee hopes that Nos. 4, 5, 6, East Crescent, are only as the cradle of an infant giant, and that it may please God to grant us to see a flourishing College of Arts, with its appropriate Scholars' Chambers, Lecture Rooms, Tutors' Rooms, Halls, Courts, and Quadrangles.

"Dr. Warneford having, with his wonted beneficence, offered the sum of £1,000 towards the objects of this undertaking; and having on various previous occasions bestowed large sums on Queen's College, your Committee trusts that it is not too sanguine in looking forward to a future Warneford College of Arts in Birmingham, worthy of that individual's venerated name, and worthy of this great town.

"10.—Your Committee is prepared, if this sketch is sanctioned and adopted by the Council, to proceed at once, should the Council empower them so to do, to draw up a detailed plan of study, and to form Rules of Collegiate Discipline for a College of Arts, such as they would strive should work advantageously in this locality, and harmonize with what has been already done, and is doing, at Queen's College.

"In conclusion, your Committee scarcely deems it necessary to point out to parents and guardians, that if such a College as that of which they have here an outline, is adopted and carried out successfully, they will have at their own doors, comparatively at a trifling expense, all the facilities and appliances of an English Gentleman's Education—from the earliest period to the age of about sixteen or eighteen at King Edward's School, and then at the Warneford College, or Queen's College (a University Education,) to the age of twenty-one, when students may obtain the degree of B.A., B.C.L., B.M., followed by the degrees of M.A., D.C.L., and M.D., and thus will be qualified, God willing, to fill any rank of life, even the highest.

(Signed) "James Thos. Law,
"John Birt Davies,
"William Sands Cox."

It was resolved that the Sub-Committee (the Principal, Lord Lyttelton; the Vice-Principal, the Rev. Chancellor Law; the Rev. Vaughan Thomas, Dr. Birt Davies, and Mr. Sands Cox,) be empowered forthwith to draw up a detailed Plan of Study, and form Rules of Collegiate discipline for a College of Arts.

NEW CHARTER OF THE ROYAL COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

Although I must confess that few subjects connected with my profession have interested me less than medical reform, I could not feel indifferent to the earnest appeal which was made in the last number of the Journal to physicians in the provinces; and I cannot refrain from complying with your request for the expression of an opinion as to the contemplated regulations in the new charter of the College of Physicians.

It appears to me that the plan has been conceived in a liberal and accommodating spirit, and that it ought to receive the frank and thankful acquiescence of provincial physicians, and especially of those who, though graduates of British Universities, are not enrolled as members of the present College. The scheme being in its main scope so open and comprehensive, I cannot but think that in one clanse there has been an oversight, as to the injustice which it would commit. I refer to the stipulation that the physicians, who are to be become Associates without examination, must have graduated *before* 1842. This restriction excludes a large number of gentlemen who have taken pains to furnish themselves with medical degrees, on the understanding that they would be thus *virtually* licensed to practise as physicians. Though not according to strict legal title, yet all the world knows that the law which enacted that none but members of the London College of Physicians should be permitted to practise, has been for a very long time a dead letter in the provinces; therefore, any one possessed of a British degree, and practising as a *bona fide* physician, may justly deem himself injured when he is called upon to qualify himself afresh for his duties, merely because his degree was obtained subsequently to a certain date. Whatever rules may be decided upon as to future qualification, there should be no retrospective legislation. I cannot see why my younger brethren, who, on the faith of their several University Degrees, have established themselves in practice, should be required to undergo a new examination. I will put a case of another kind, which is not a hypothetical one. A general practitioner of considerable experience, distinguished for his talents and his extensive acquirments, in science and literature, and moreover a hospital surgeon, was obliged, by reason of ill-health, to retire for awhile from the exercise of his profession. When better health returned, he determined upon confining himself to medical practice, and he therefore procured a degree from a Scottish University. This degree was given after a severe and searching examination, such as requires some moral courage and determination on the part of a man of middle age who subjects himself to it. The gentleman alluded to has been practising as a physician for three years, and during the greater part of that period has filled the office of physician to a public medical institution. Surely it would be very hard to compel him to undergo another

ordeal before he could become an Associate of the College, and consequently before he could be registered as a physician.

I feel confident that as the limitation in question is inconsistent with the generous and conciliatory spirit which pervades the proposed plan of the new charter, the framers of the latter will be easily induced to withdraw the objectionable clause. To me it has seemed to be a duty to direct attention to it, because I am not personally interested in the matter, while those who are so, may feel a difficulty in urging their claims.

I cannot conclude this brief letter without avowing that I entertain so high a respect for the College of Physicians, ennobled as it is by the most illustrious names in British medicine, that I should be proud to find myself associated with it according to the proposed scheme. Graceful concessions ought to be accepted cheerfully, and even gratefully.

I am, Sir,
Your obedient Servant,
J. A. SYMONDS, M.D.

Bristol, March 14, 1848.

THE BILL FOR PROMOTING PUBLIC HEALTH.

To the Honourable the House of Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled.

The humble Petition of the undersigned legally qualified Practitioner in Medicine, Surgery, and Midwifery, of the City of Bath,—

Sheweth,—

Your petitioner is of opinion that questions relating to the public health, have not hitherto received from the Legislature of this country, the degree of attention which is commensurate with their importance, he therefore regards with great satisfaction the introduction into your Honourable House, of a bill, entitled a "Bill for promoting the Public Health.

That while your petitioner highly approves of many of the provisions of this bill, he has observed with deep regret and disappointment the entire omission of, or allusion to, the medical profession. This omission will not only be most grievously and keenly felt by the members of the medical profession, but will be attended with very serious and injurious consequences to the community at large.

Your petitioner begs respectfully and earnestly to remind your Honourable House, that the care and due conservation of the public health legitimately belong to the members of the medical profession; and they have not only the responsible and difficult duty of treating the various disorders to which the human frame is liable, and frequently risk their lives in their attempt to alleviate malignant and pestilential diseases, but they are also expected and often called upon to devote much of their valuable time, talent and industry, and by persevering application, endeavour to discover the causes and what has a tendency to prodnce them.

Your petitioner is of opinion, therefore, that any bill or scheme which has for its object the promotion of the public health, will be exceedingly defective, that does not admit or provide for the appointment of legally-qualified members of the medical profession to share and assist in its due administration.

Your petitioner therefore earnestly and respectfully prays your Honourable House to supply this defect in the proposed bill, and to insert a clause which shall require one or more members of the medical profession to form part of the General Board of Health, and also to appoint a medical superintendent wherever the bill for promoting the health of towns may be in operation, and your petitioner will ever pray.

GEORGE KING.

Bath, February 24, 1848.

[The foregoing petition has recently peen presented to the House of Commons, and is important as directing attention to a defect in the measure which, unless remedied, will render many of its more important provisions altogether nugatory.]

BAPTISM OF SICK INFANTS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

May I beg the favour through the medium of the *Provincial Journal*, of enquiring of my professional brethren, how they are in the habit of treating certain applications made to them under the following circumstances?

It appears that the clergy in the diocese of Norwich, and, most probable, the same is the case elsewhere, are instructed that the baptism of infants shall only be performed in strict conformity with the rubric, and that the practice of a preliminary baptism or "naming," as heretofore customary, should be discontinued. In complying with this ordinance, the clergy, as if by a mutual understanding, have set apart one Sunday in each month, and it is expected all children born in the intervening period, shall on this day be brought to the font, attended by the required sponsors. Now, it happens not unfrequently, that an infant is attacked with sickness previous to the advent of this important day, and the parents, anxious to secure it a christian burial, and perhaps, if imbued with faith in the doctrine of baptismal regeneration, dreading the death of their infant unregenerate, apply to the minister to have it baptized. The answer is—"Unless you bring a certificate from a surgeon, stating that the child's life is in imminent peril, the rite cannot be performed." Hitherto I have declined giving the necessary document, as I can only regard such a demand on the part of the clergy as tending to fasten unduly a solemn responsibility on the medical profession, which naturally belongs to themselves.

I am, Sir,
Your most obedient servant,
JAMES COOPER.

Filby, Great Yarmouth, Norfolk, March 3, 1848.

Medical Intelligence.

APPOINTMENTS.

Ewing Whittle, Esq., has been elected Surgeon to the North Dispensary, Liverpool.

The Honorary Degree of Doctor of Medicine has been conferred, by the University of New York, on Henry Marshall, Esq., of Edinburgh, Deputy Inspector General of Army Hospitals, and on William Farr, Esq., of the General Register Office, London.

ROYAL MEDICO-CHIRURGICAL SOCIETY.

Tho following gentlemen were elected officers of this Society at the Anniversary Meeting, held on Wednesday, March 1st:—*President:* James Moncrieff Arnott, F.R.S.—*Vice-Presidents:* Henry Davies, M.D.; Jonathan Pereira, M.D., F.R.S.; George Macilwain; Richard Partridge, F.R.S.—*Treasurers:* Benjamin Guy Babington, M.D., F.R.S.; Benjamin Phillips, F.R.S. —*Secretaries:* William Baly, M.D., F.R.S.; Fred. Le Gros Clark.—*Librarians:* John Hennen, M.D.; Richard Quain, F.R.S.—*Members of Council:* James Alderson, M.D., F.R.S.; Thomas Mayo, M.D., F.R.S.; Robert Nairn, M.D.; William Sharpey, M.D., F.R.S.; Leonard Stewart, M.D.; Henry Ancell; Richard Blagden; George Busk; John Dalrymple; James Paget.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members, Friday, March 3rd, 1848:—J. H. Bennett; R. Turton; J. W. Cleave; T. R. B. Isaac; E. F. Sankey; E. B. Gaylard; G. Dunn; J. L. V. Gregory; G. H. Macnamara; J. G. Wilson.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, March 2nd, 1848:—Edward Fitzwilliam Sankey, Dover; Arthur Robert Pedgrift, London; John Evans, Sunderland; Richard Marley.

Thursday, March 9th, 1848:—John Samuel Pearse, Gateshead; Edward William Plews; Prosper Felix Louis Napoleon De Larné, Devonport; Charles William Bloxham, Halesowen; Edwin Thomas Watkins, R.N.

OBITUARY.

Died, August 31st, 1847, at Oatlands, Van Diemen's Land, F. J. Park, Esq., Colonial Assistant Surgeon, and Medical Officer of that district.

February 14th, at South Molton, Devon, aged 52, John Nott Harding, Esq., Surgeon.

February 26th, at Tinnehely, County of Wicklow, of fever, Henry Morton, M.D.

February 26th, at Sheerness, aged 47, George Walker, Esq., Surgeon.

March 2nd, at Brighton, Robert Murray, Esq., Surgeon, Honourable East India Company's Service.

March 5th, at Frankfort-on-the-Maine, aged 48, Ynyr Burges, M.D.

March 6th, at Shanklin, Isle of Wight, aged 54, Alexander Home Renton, M.D., late of Madeira.

March 12th, at Manchester, aged 25, of fever, Joseph Done, Esq., one of the Visiting Medical Officers to the Manchester Royal Infirmary.

March 13th, at Bangor Infirmary, of typhus fever, W. Leyson Thomas, Esq., House Surgeon to that Institution.

Lately, James Lewis Kirkness, Esq., Surgeon, Truro.

NEW CARTER OF THE ROYAL COLLEGE OF PHYSICIANS.

NOTICE.

It is requested that gentlemen, sending communications on the subject of the proposed Charter of the Royal College of Physicians, will attach their signatures, as letters which are not so authenticated cannot be laid before the Council of the Provincial Medical and Surgical Association, and will consequently fail of their object. All such communications will, if desired, be considered confidential.

ROBERT J. N. STREETEN, M.D.,
Secretary to the Association.

TO CORRESPONDENTS.

Communications have been received from Dr. Oke; Mr. J. Cooper; Mr. G. Bullen; Mr. G. King; Mr. Ross; a Physician; Mr. S. S. Dyer; Mr. Crompton; a late Provincial Physician; Mr. S. J. Salter; Mr. T. Hunt; Dr. Symonds; Mr. T. Pope.

PROVINCIAL
MEDICAL & SURGICAL JOURNAL.

CLINICAL LECTURE ON DIABETES AND ON CHOREA,

Delivered in King's College Hospital, London,

By R. B. Todd, M.D., F.R.S., Fellow of the Royal College of Physicians, &c.

(Reported by S. J. A. Salter, Esq., M.R.C.S.)

Gentlemen,—In the last clinical lecture I delivered to you, I entered upon the subject of diabetes, only so far as its history and pathology: I come to-day to consider the *treatment* of this malady.

In the observations which I made upon the pathology of diabetes, I pointed out to you that the great question which yet remains for solution, is as to the source of the sugar,—whether the sugar produced is simply a conversion of saccharifiable parts of the food; or whether it be not in part also a product of secretion, or of the changes which occur in the secondary assimilative processes. Now, I would remark, that there is nothing far-fetched in the notion, that sugar may be secreted or developed in the secondary assimilative processes. During lactation sugar is secreted in considerable quantity by the mammary gland; and the sugar of milk resembles in its constitution that of diabetes. Moreover, the proportion *per cent.* of sugar in milk is, in general, I believe, much greater than that of sugar in the urine. I know of no accurate estimate of the quantity of milk secreted by the human female in twenty-four hours, but judging from the quantity which an infant can drink in that time, I should say it cannot be less than two or three pints, which would yield a considerable quantity of sugar.

For all practical purposes we may, in the present state of our knowledge, adopt with advantage the following view of the pathology of diabetes:—that it is primarily a disease of the mucous membrane of the stomach, whereby an abnormal diastase is formed, which readily converts into sugar such aliments as admit of that conversion; the mucous membrane probably likewise secretes sugar; the sugar thus formed passes into the blood, and is rapidly eliminated by the kidneys, causing at the same time the attraction to those organs of the elements of a large quantity of water. This theory essentially agrees with that put forward many years ago by our countryman Dr. Rollo, who was the first to point out theoretically as well as practically the importance of a diet, consisting mainly of animal food in this disease.

In describing to you the treatment of diabetes, I shall consider the subject under two principal heads,—namely, the treatment which consists of alteration and restriction of diet, and that which is effected by the use of certain drugs or other therapeutical agents. In the *first* place, from the fact that starchy matters are capable of being converted into sugar when submitted to the action of saliva, and of certain other organic matters, we are at once led to the opinion that the amylaceous food should be removed from the patient's diet as much as possible. Of the articles of food in ordinary use, bread and potatoes contain the largest quantity of starch; the latter should altogether be forbidden, as they consist almost wholly of starch, and contain very little of any other substance that is of service in nutrition; bread, however, contains gluten, a highly nutritive nitrogenous substance, and as patients cannot be wholly deprived of carbonaceous food, bread is the best to choose, on account of the gluten which is thus mixed with it.

It has been proposed to give gluten bread, which consists of the gluten of flour from which the starch has been carefully removed; but it is a dry, insipid, bread, and it is very difficult to induce patients to take it for any time, so that, however, upon theoretical grounds, it may appear desirable, it is practically of very little value.

You will find it, in general, a better plan to give your patients brown bread instead of white; and the coarser it is, and the more bran it contains, the better. Bread of this kind has with most persons a laxative effect, which is a great recommendation to it.

Sugar, and vegetables containing starch, should be altogether avoided; but those vegetables which do not contain starch, may be taken with much advantage, for by that means the diet is capable of being varied; thus great relief may be given, to the discomfort of which the patients complain when their food is too uniform. Such vegetables as celery, lettuce, greens, cauliflower, are those to which I refer. Fatty substances and butter, which from their non-nitrogenous character may possibly admit of conversion into sugar, should also be avoided.

But while we are depriving our patients of one sort of food, we should be careful that he is supplied with that which will not be injurious to him; he should take the protein compounds, albumen and fibrin, and also gelatine, in the form in which they are met with in different kinds of animal food. It is doubtful,

however, whether even these are not sometimes converted into sugar.

Bouchardat maintains that this never happens; but I incline much to the opinion, that even when the diet consists of nitrogenous food alone, some sugar will be developed, either in primary or secondary assimilation.

The quantity of food which these patients take should be large, on account of the great waste which is going on in their bodies; they should take meat, fish, or eggs, two or three times a day, or more frequently if necessary.

In making these observations as to the power which the stomach possibly has, in diabetes, of converting the protein compounds into sugar, it must be remembered that these substances are never eaten in a state of absolute purity. Meat and eggs contain oil and fat, which in composition are nearer that of sugar than of protein compounds, and which, according to some chemists, are transformable into sugar, and although they occur in but small quantity in these substances, still it is quite enough to throw some doubt and uncertainty over our observations.

With this tendency to generate sugar in the stomach there seems to be an absence of power in the organ to digest it, and so it is absorbed unchanged into the circulation; or else so large a quantity is generated, that a large proportion of it eludes the influence of the digestive organs. In people in health, when sugar is taken into the stomach in moderate quantity, it is probably immediately disintegrated by the digestive process, either in the stomach or in the intestinal canal, and exist no longer as sugar. The question arises—are there any means by which the stomach or duodenum can be made to digest the sugar that is thus abnormally generated within its cavity? This point has been overlooked by Bouchardat and others. I know of no direct means by which this object can be immediately accomplished, but the powers of the stomach may certainly be improved by the use of appropriate medicines.

This brings us to consider that part of the treatment of diabetes which consists in the use of therapeutical agents, and of these I shall first notice those commonly called tonics. Both mineral and vegetable tonics may be employed with advantage. The mineral acids,—the sulphuric and muriatic, may be used. Gentian, quassia, and chirayita, are good vegetable tonics to employ in diabetes, but I have a decided preference for the latter. Chirayita is an Indian plant and has long been used in the east, under the same circumstances as we use the vegetable bitters in this country; it has the advantage of not producing the constipation, which other vegetable tonics so frequently do, and as constipation is a symptom very generally met with in diabetes, it is advisable not to employ any medicine which is likely to increase or confirm that condition.

Opium is a very important medicine in diabetes; its beneficial action is partly by its influence on the skin, producing diaphoresis, partly also from the soothing power it has over the nervous system, which is generally more or less irritable; it also allays the craving of the stomach, so that the patients do not eat so much; and as the thirst is in proportion to the quantity eaten, it likewise becomes diminished when less food is taken. On the whole, perhaps the most favourable form in which opium may be given, is that of Dover's powder. But you will do well to be cautious in the use of this remedy, and to bear in mind Dr. Prout's suggestion, that by the prolonged use of opium, your patient may become an opium-eater, and be unable to exist without it.

Baths of different kinds are also useful in diabetes; they serve to keep the skin clean, and so to assist other diaphoretics. The hot-water bath, the cold bath, and the hot-air bath, are each recommended; and the latter has been particularly extolled by some physicians. It must, however, be kept in view that the hot-air bath is an agent of great power, and exerts a very depressing influence upon the system, after it has been several times repeated. What I have found to be the most useful mode of applying the bath is this:—to put the patient in the hot-air bath; when he comes out to dash cold water upon him, and then have him thoroughly rubbed with a rough towel until he is dry, and a glow of heat is produced; this being done he is instantly put to bed. The cold water thus used has a stimulating and invigorating effect, and which seems to counteract the depressing influence of the hot-air bath, without interfering with the amount of perspiration. One of our patients, Hardy, used the hot-air bath in this way, and derived so much benefit from it that, of his own accord, he persevered in its use for a considerable time. I may here remark, that I have found this mode of using the hot-air bath very beneficial in some forms of dropsy, with albuminous urine. Another method is to put the patient in a hot bath in the morning, and if it make him perspire too freely, then to put him in a cold one in the afternoon.

The solution of *pepsin*, in imitation of the gastric juice, is a remedy which was, I believe, first suggested by myself: it often assists digestion. I give it immediately before or after a meal, and although I have seen no direct influence that it exerts upon the amount of sugar generated, still it seems to improve the patients' powers of primary digestion; they are better nourished, and they tell you they are sensible it does them good, and on this account they beg for its continuance, but it undoubtedly exercises no direct influence on the generation of sugar. It is made by digesting the thick dark portion of the mucous membrane of the pig's stomach in distilled water, slightly acidulated with muriatic acid, at a temperature of 100°, for from twelve to twenty-four hours. The best test of its goodness is, its power of digesting meat and albumen, when kept at the same temperature for a few hours.

A remedy which will exercise a direct influence upon the peculiar state of the organs of primary digestion, which accompanies diabetes, is, as yet, a desideratum. Many other remedies, besides those I have mentioned, have been tried, and with some benefit; of these I may specify magnesia, ammonia, creosote; none of them, however, is entitled to be regarded as peculiarly efficacious in the disease. You will do well, however, to

keep them on your list of remedies, for in the treatment of a tedious and chronic malady, such as this, it is well to have the means of changing the remedy from time to time, and so to keep up your patient's hope.

As to the use of alcoholic stimulants, it may be said, that employed moderately, they exercise no unfavourable effect on diabetes, and you must be guided in your employment of them by the feelings of your patient, and the peculiar circumstances of each particular case.

I here terminate my remarks on diabetes. In another lecture on this subject, I will describe to you the results of the treatment of our patients Hardy and Bowles, who are now placed in a separate ward, under careful surveillance, for the purpose of being subjected to a strict animal diet.

CHOREA.

I shall occupy the remainder of this lecture, gentlemen, by offering to you a few remarks upon that remarkable disease of the nervous system—*chorea*, of which we have a very good example at present in the hospital. Amelia Reynolds is the patient to whom I refer; she was admitted into Augusta Ward, on November 2nd; the following is the account given of her in the case-book:—"She is 15 years of age, native of London, where she has always lived; last January, had inflammation of the lungs, and, soon after, sore-throat, from these she entirely recovered. States that six weeks ago her present complaint came on, with violent headache, deafness, vertigo, and almost entire loss of sight at times; at the same time she became restless, and lost the power of properly governing the movements of her limbs, especially on the left side. For this she applied to a medical man, who ordered six leeches to be applied to her temples, low diet, and change of air. From this time she became worse. She menstruated first about twelve months ago, but has not been unwell for the last eight months, though she has at times been troubled with pain in the loins and lower part of the belly." Such is the history of her case, and the following is the description of her present condition:—She has incessant fidgetting movements, which are not properly directed by volition; they are confused, irregular, jerking, and, although apparently performed with considerable vigour, yet they are not co-ordinated. Articulation is affected, she speaks quickly and snappishly; when told to put out her tongue, she does it in the same jerking manner as she moves her other muscles, with a peculiar thrust, projecting nearly the whole organ. This peculiar action of the tongue is a constant and very characteristic symptom of chorea; it is an early symptom, by which I have been led to suspect the approach of an attack of chorea, before any other symptom had made its appearance. These movements go off during sleep, and return immediately on waking—a fact of singular interest. Mental excitement causes an increase of these jactitating motions, and so does any attempt to restrain them, as holding or tying the limbs down. There are now no symptoms affecting the organs of sense, but when the disease began there was vertigo, with headache.

The disease generally commences simply with disordered general health, imperfect digestion, which causes an impaired condition of the blood; this state of things is followed by slight fidgetting only at first, or irregular movements of particular parts,—a hand, or leg, or the face,—which subsequently pass into those of confirmed chorea. In other instances, and these are very common, it may clearly be traced to some sudden fright which the patient has had, and this may bring it on in a person who has, or has not, been in a previously cachectic condition; but chorea coming on in an individual who was apparently in good health, and who has not been subject to fright, is extremely rare.

This disorder is peculiarly interesting, because it is strictly emotional in its character, and has its seat in those parts of the brain which preside over emotion. When a person, not suffering from chorea, is suddenly frightened, he is immediately impelled to make certain irregular jerking motions, which endure for a variable time, in proportion to the excitability of the subject; and these, while they last, are not at all unlike the movements of chorea. A peculiar feature in the movements of chorea is, that they are always more or less one-sided; they are not necessarily confined to one side, but are more remarkable on one side than on the other. Sometimes they are strictly limited to one side. Chorea may be conveniently divided into two kinds, according as the jactitations are *general* or *partial*; the former when all the limbs are affected, and the latter when it is confined to some of them only.

General chorea is an extremely dangerous disease; patients suffering from it are unable to stand; they are therefore obliged to keep in the recumbent posture, and as they lie in bed, shake and jerk, and throw themselves about, till they rub off the cuticle of those parts which come in contact with the bed, and at length they die from sheer exhaustion; they literally shake themselves to death; our patient, Amelia Reynolds, presents a *mild* example of general chorea.

Pathology.—What we know of the physiology of the encephalon, points to that organ as being the seat of the disturbed function in chorea; *post-mortem* investigation, however, displays no organic change. Various morbid conditions of the nervous centres have been found in some cases, but these are evidently only accidental combinations; thus, patches of bone on the arachnoid of the spinal cord and brain have been seen, cicatrices of the ovaries, and many other morbid appearances. None of these, however, are constant, nor have they any obvious relation to the parts whose functions are disturbed. Indeed, I believe it may be confidently stated, that chorea is a strictly functional disease, entirely independent of any organic lesion appreciable by our means of observation, and that it occurs in connection with depraved nutrition, just as we see various nervous symptoms arise in hysteria, as, for instance, paralysis, where the body is in a similarly ill-nourished condition. In cases of hysterical paralysis, the symptoms are most probably produced by the depraved or deficient nutrition, affecting principally some portion of the nervous system most intimately connected with the part paralysed.

In chorea the whole nervous system appears to

participate in this disordered state of nutrition, but more especially those portions presiding over emotion, namely, the upper part of the medulla oblongata and the mesocephale, and this I believe constitutes the essence of the disease. I have pointed out to you the one-sided nature of this affection, and you have seen that in the case in the hospital we have just been considering, it is the *left* side that is chiefly affected; this unilateral character shows that it is a brain-disease and not one of the spinal cord, as some have supposed, for diseases of the spinal cord affect both sides alike.

The opportunities of making *post-mortem* examinations in cases of chorea are extremely few, for the natural tendency of the disease is to get well, and in a large proportion of the cases recovery will speedily take place, with merely good diet, pure air, cleanliness, and a little purgative medicine; and this, by the way, affords an additional proof that the malady is dependent on impaired nutrition, as all these means have a tendency to bring about a healthy nutrition, and to render it vigorous. Another proof of this may be derived from the morbid state of the urine which sometimes accompanies the disease; it is often of high specific gravity, and in other cases it contains a super-abundance of phosphates; the specific gravity sometimes ranges from 1030 to 1038, even when the urine is in pretty good quantity. On the 11th of this month our patient, Amelia Reynolds, passed urine of specific gravity, 1038; on the 13th, 1033; on the 14th, 1022; and on the 17th, 1026.

Treatment.—By far the majority of cases are of a mild kind, and very amenable to treatment. In the first place, the patient should have plenty of nourishing food, especially animal food, and such as is easily digestible; pure open air is also necessary. Purgatives are very useful, and when you are first called to a case of chorea, it is a good plan to give purgatives for two or three days, so as thoroughly to clear out the alimentary canal, but the purgatives should be of a mild kind, and not such as have a tendency to lower the patient's strength, and be used simply to unload the alimentary canal, and to get the secretions into a healthy condition, and this very often will alone suffice to accomplish the cure. After this kind of purging has been used, a systematic course of tonics must be adopted, and they will almost infallibly destroy the disease; all the tonics are of nearly equal value, but sometimes it will be found that one will fail, and that upon giving it up and trying another, the patient speedily has relief. Some prefer metallic tonics, as zinc, iron, or arsenic, but I prefer the vegetable tonics, and of these, quinine; and if there is much anæmia and pallor, I would add to it some preparation of iron. I seldom give arsenic; it is a very powerful medicine, and may do much harm, while all that is wanted can be accomplished by other means; it may produce a state of system which will render the patient miserable for the rest of life; it should not be employed unnecessarily or unadvisably, and only in extreme cases, and where other tonics have been used in vain.

The cold bath is a very useful means to employ; it must, however, be used with great caution, or it may even do harm; it must be remembered that the complaint is one of emotion, and that a too sudden plunge into cold water, or a too abundant affusion, may frighten the patient, and increase the disorder; but the general effect of bathing is a marked improvement in all the symptoms.

In obstinate cases, which resist all modes of treatment, the use of electricity, as developed from the electrical machine, has been found of the greatest benefit.

MEMOIR ON TURNING, AS AN ALTERNATIVE FOR CRANIOTOMY AND THE LONG FORCEPS, IN DEFORMITY OF THE BRIM OF THE PELVIS, &c. &c.*

By J. Y. Simpson, M.D.,

Professor of Midwifery in the University of Edinburgh.

Sect. VII.—Physiological and Pathological Reasons for the Life of the Child not being necessarily compromised under the Proposed Practice.

It has been alleged that the preservation of the life of the infant is not compatible with its forcible extraction by turning through a contracted pelvic brim. It must perish, it has been argued, in consequence of the lesions it necessarily sustains, and especially—1st, in consequence of the injurious compression to which its head is subjected during the forced delivery; and, 2nd, in consequence of the required injurious traction upon its neck. Let us examine, in detail, each of these alleged necessary causes of death to the child under the practice in question.

1. Is the Compression to which the Infant's Head is subjected Incompatible with its Safety and Life?

In the remarks which I offered under the last section, with regard to the question whether in turning in contracted pelves the degree of injury to which the child's head is subjected, is or is not compatible with its future safety and life, I confined the observations which I made, and the illustrative cases I adduced, to that form of cranial lesion in which the sides of the fœtal skull are both compressed and indented. In some instances, however, even when the pelvis is much distorted, one of these states only, as the lateral compression alone, *without* the indentation of the cranium, is all that is required in order to reduce the head to the size necessary for its transit. On one occasion, a pelvis, the conjugate diameter of the brim of which was less than three inches, from projection of the promontory of the sacrum and disease of the symphisis pubis, I extracted a full-grown infant by turning; the head passing through in a flattened and compressed form, but

* Continued from page 144.

without any depression or indentation upon it. It is, I believe, unnecessary for me to prove, that when the extraction can be effected with this single lesion, the child is not necessarily sacrificed; because I have already proved, that even when the two lesions of compression and indentation co-exist, the presence of both forms of injury is not necessarily incompatible with the continuance of life. And sometimes by compression alone, more especially if the skull is not very fully ossified, the fœtal head may certainly be very greatly reduced in size without compromising life. Dr. Denman conjectures that, to quote his own expression, "it may be reduced one-third below its original size, without the destruction or even injury of the child from the compression."*

It would, however, be improper to leave this subject without attending to some anatomical and physiological circumstances, in the structure of the fœtal head, that enable it to bear this great degree of lateral compression which we have been considering, without the necessary destruction of life. Indeed, perhaps the very knowledge of these circumstances may impart to the mind greater faith in the correctness of the principles of the proposed practice.

We shall afterwards have occasion to see that by far the most frequent form of morbid contraction of the brim of the pelvis consists in the projection forwards of the promontory of the sacrum, and this is a kind of distortion specially adapted for the artificial delivery of the mother by turning, instead of craniotomy. Under this kidney-shaped pelvic brim, and other varieties of pelvic contraction, when the child is delivered by turning, the direction of the compression of the head is, as we have already found, lateral and transverse, or, in other words, in the line of its bitemporal or biparietal diameters, these diameters being reduced and shortened by it.

Now, of all directions, the *lateral* is the one in which the child's head can endure the greatest degree of compression, with the least degree of danger. The power of diminution of the child's head under labour "is greatest," observes Dr. Ramsbotham, "in the lateral diameter, and," he continues, "a full-grown fœtal head may be lessened from side to side, without endangering the child's life, one-seventh of its own extent, or from three inches and a half to three inches."† Dr. Ramsbotham states that this degree of compression of the head,—namely, to one seventh, may be accomplished without the life of the child being endangered. We have just now seen that Dr. Denman imagines that the amount of compression may be carried much farther,—namely, to one-third, without the life of the child being necessarily injured and destroyed. No author has pointed out more correctly than Dr. Radford, the fact that the child's head will bear, with comparative safety, a far higher amount of compression in its transverse or biparietal diameter, than in its longitudinal or occipito-frontal diameter. When the head is compressed in the first of these modes, or transversely, "the brain,"* he observes, "bears this alteration in the figure of the cranium with comparative little inconvenience, because the pressure it sustains is parallel with the fibres of some of those parts which lie between the two hemispheres, and with the falx, which in its natural state supports this organ. The pressure is also less injurious, because it is applied upon the sides of the vessels, but not in such a degree as considerably to influence their calibres." When, however, the direction of the pressure happens, as in the opposite or longitudinal axis of the head, the results are very different, and far more dangerous. Then "the alteration," Dr. Radford remarks, "which takes place in the head, is as follows:—A considerable diminution in the length of the occipito-frontal diameter is produced, in consequence of approximation between the frontal and occipital bones; the fontanelles become nearly obliterated, and the sagittal suture is wider and more prominent. The brain is pushed into this space, which is insufficient for its accommodation; its organization is injured, and the child, when born, is either dead or dies soon after birth. The pressure applied to the fore and hind part of the head has a tendency to change the relative situation of many parts of the brain. It forces one hemisphere from the other, which if carried beyond a certain degree, will inevitably produce laceration of the coats of the veins which pass to the longitudinal sinus; and this danger is increased by the great congestion which exists. These serious effects," he again states, (viz., apoplectic congestion, sanguineous effusion, and softening of the brain,) "are produced by the brain being compressed in a direction contrary to the course of the fibres of some of those parts which lie between the hemispheres, and also to the current of blood along the longitudinal sinus." Dr. Radford adds, that injuries of this character are sometimes met with when the head has been compressed and dragged through the pelvis with the long forceps; and he gives two dissections of the fœtal encephalon to shew these results, (congestions, effusions of blood, &c.,) in two cases in which the delivery was accomplished by this instrument. The cause for instrumental delivery and the application of the long forceps is not specified in one of these cases; in the other they were used on account of distortion of the brim of the pelvis. And certainly, if we employ the long forceps to overcome this difficulty, and place them as Deleurye, Haighton, Davis, Ramsbotham, and other excellent operators have recommended, with one blade over the face or

* "Introduction to the Practice of Midwifery," 1816, p. 352.

† "Obstetric Medicine and Surgery," p. 25.

* "Essays on Various Subjects connected with Midwifery," p. 7, &c.

forehead and another over the occiput of the child, we, in our extractive efforts, must compress the fœtal head with the instrument so applied in its longitudinal or antero-posterior axis; and hence the actual direction of our pressure would endanger the child more than the actual degree of it. If, in the same case, and under the same obstruction, however, the child were extracted by turning, the required reduction of its head by being effected entirely by lateral compression, would be effected, as we have already seen, not only with much greater facility but with much greater safety to the infant; and the chance of injury of the brain and of congestion and sanguineous effusion upon it would be greatly less.

But, though the danger of cerebral congestion and its effects is diminished in lateral, as compared with longitudinal, compression of the child's head, yet it is by no means abrogated and removed; and in these cases of lateral compression and indentation of the cranium, which, under either footling or head presentations prove fatal, it is this *effusion* and its dangers, more than the mere *compression* of the proper structure of the brain, that seems to lead to this result. At all events, the cases I have already cited, in the last section, shew that the cerebral tissue may be compressed, or at least displaced, in a lateral direction by the grooved and depressed cranium, not only without destroying or endangering life, but without producing coma or convulsions, or any greater lesion of function than a mere temporary asphyxia, provided always there be no serous or sanguineous congestion and effusion accompanying and resulting from it. The escape of the infant under this form of injury in which we are thus interested, is favoured by other circumstances. When the fœtal skull and encephalon are decreased by pressure in one diameter, they become lengthened and increased in others. In the form, for instance, of lateral compression resulting from extraction through a distorted pelvis by turning, while the head is flattened and diminished in its transverse diameter, it is temporarily lengthened to a corresponding degree in its vertical and longitudinal diameters. The anatomical peculiarities of the fœtal skull, the existence of fontanelles and sutures between its component bones, and the consequent isolation and mobility of the individual bones themselves, freely admit of this; and so far under cranial depressions no doubt save the proper tissue of the brain from a deleterious and destructive amount of pressure in a way that, under the same form of injury, would be quite unavoidable with the cerebral contents of the solid adult cranium. Besides, the immunity of the infant at birth under such apparently severe injuries, may partly be owing to another and a physiological cause. The embryo and fœtus possess a much lower physiological type of life than that which pertains to the adult; nor is the transition from the one to the other abruptly and entirely completed when the infant passes from its intra-uterine to its extra-uterine existence. It is stated by Billard,* and I could quote no more accurate observer, that symptomatic fever seems incapable of being excited in the constitution of the infant by injury or otherwise till the time of teething; and in all probability lesions such as these to which the crania and encephala are subjected at birth in the class of cases we have been considering, are less dangerous and fatal in their effects, in consequence of the general law, that the power of resisting and repairing injuries is greater in proportion as the type of animal life is lower. It is true, besides, that individual infants, like individual adults, have a power of withstanding injuries much more than others, and in a way that it is impossible to account for on any known principles.

Speaking of the differences among children in relation to the danger they incur, from compression of the head during labour, Jacquemier remarks,—"One infant, of a feeble constitution, will resist a long compression by the parts of the mother, or by the energetic and reiterated action of the forceps; another, of a strong constitution, whose head has not been a very long time, or very strongly, compressed by the pelvis, or between the blades of the forceps, readily dies, or only has a few hours' existence."†

Lastly, let me observe that the kind and degree of ossification of the bones of the fœtal cranium at birth admit of their yielding and becoming depressed in a manner that no doubt contributes to the safety of the infant. The ossification is as yet, in general, so imperfect that the flat individual bones, such as the parietal and frontal, are still sufficiently thin and flexible to allow of their being partially indented and altered in shape by strong pressure applied to one point of their surface. They are at the same time usually so elastic as easily to be made to regain their former shape. And this indentation and restoration may occur without any appreciable fracture. In the first case which I have related, the right parietal and frontal bones, when their external surface was carefully examined after the removal of the scalp, were found deeply depressed but apparently not fractured. They afterwards fissured, however, at the site of the indentation when being dried and prepared for preservation. However, if the indentation is extremely deep or the bones unusually ossified, no doubt fracture will take place, but still probably without danger, if without internal or encephalic effusion.

We have found Velpeau, and the other authors we have quoted, generally stating that the compressed cranium, and especially depressed portions of it, usually become

* "L'absence de toute réaction fébrile, lors même qu'il existe des lésions graves chez les nouveau-nés; la promptitude, au contraire, avec laquelle la fièvre s'allume par la moindre cause chez les enfants qui ont dépassé l'âge de la dentition, imprime aux maladies de ces deux époques un caractére différentiel de la plus grande importance."—*Maladies des Enfans. Preface, p. 2.*

† "Manuel des Accouchemens," p. 770.

spontaneously replaced and restored in the course of a short time after birth. This is, however, not always the case; nor is its occurrence absolutely necessary for the viability of the child. In evidence of this I shall content myself by citing a single illustrative case.

Case XXVII.—In the course of the last winter, after lecturing on the subject of these indentations in the fœtal cranium, one of the students in my class, afterwards shewed me, on his own person, two deep impressions, one on each side of the cranium, which had been produced by the use of the forceps, and which had afterwards continued permanently depressed. He was 20 years old. On the right side of the head, a little above the ear, there were two pretty deep, curved fissures or indentations from two to three inches long. On the left side there was a single shorter indentation above the commencement of the temporal ridge.

2. Is the Traction to which the Infant's Neck is subjected Incompatible with its Safety and Life?

The answer to this inquiry need not detain us long; in fact, the proper reply to it has already been virtually given, when considering whether the existing degree of cranial compression and indentation was necessarily fatal or not. For if, as we have found, children can survive after being turned and extracted through so narrow a pelvic brim, that the sides of their crania are sufficiently collapsed and depressed against the sides of the contracted maternal pelvis, to admit of the complete transit of the head, then it is evident that the neck is not fatally injured under the proposed traction; for in all these cases the degree of traction upon it was adequate to produce all the results wanted, without destroying the child. In these instances the extractive force necessary to drag the head through the contracted pelvis was applied to the neck, and the neck was found sufficient to bear it without compromising the life of the child; and I believe, as I have stated previously, that this will generally, if not always, be found to be the case, "provided the child be living, or only lately dead." It will be very different, however, if the child has been for some time dead, and decomposing; the structures of the neck, certainly, will not then bear such traction as is required to extract a full-sized head through a distorted brim; nor is it of any practical importance that it should, for such cases are cases for craniotomy, the child being dead, and forming no element for consideration in the mode or kind of delivery that is followed.

But, independently of the above decisive and conclusive testimony, and even if it were wanting, it would be easy, I believe, to adduce such cases and observations from obstetric clinical reports and other works, as would, *a priori*, have rendered probable what these cases render certain,—viz., that the degree of traction to which the child's neck is subjected under the proposed practice, is compatible with its safety and life. I shall, for the sake of brevity, confine my illustrations of this remark to a note or two of some cases recorded by Dr. Smellie, and some observations offered by the ever-cautious Dr. Denman. Dr. Smellie gives various cases in which he was evidently himself astonished, as other practitioners have often been, at the excessive degree of traction which the neck of the infant stood during delivery in natural or artificial pelvic presentations, without the life of the child being compromised by it. For example:—

Case XXVIII.—In a breech case, where the woman was long in labour with a large child, and was suffering from some hæmorrhage, Dr. Smellie brought down one foot, extracted the body and extremities, but the progress of the delivery was "stopped at the head," and required much traction for its transit, Dr. Smellie being "obliged to increase the force every attempt." "I pulled," he observes, "so long, and with so great force, before the head was delivered, that I was surprised to find the child alive." (Collection 32, Case 10.)

Case XXIX.—In the next instance which he reports, one of the breech presenting in a narrow and distorted pelvis, after the body of the child was born, Dr. Smellie brought down the right arm, and "helped down the forehead; but," he adds, "before I could deliver the head, I was obliged to bring down the other arm, and saved the child also, although a *good deal* of force was used to deliver the head." (*Ibid.*, Case 11.)

Case XXX.—A young woman, of "a small size," was in her first labour. The thighs of the child, which was large, presented. The labour was very slow and lingering. Dr. Smellie brought down the feet, and effected the extraction of the infant. "I delivered," he remarks, "the head, but not without a good deal of force. The child was alive, which I scarcely expected." (*Ibid.*, Case 18.)

Case XXXI.—The breech presented, and the pelvis was narrow, and the child was born living. In attempting to deliver the head, Dr. Smellie tells us,—"I imagined it was impossible the child would be alive, as I found the neck was so over-stretched," having met "with greater difficulty than any that I ever delivered in that manner." (*Ibid.*, Case 13.)

In his classical and highly practical introduction to midwifery, Dr. Denman has devoted a special section to the consideration of the practice to be followed, in order to extract the head through the brim, in cases in which preternatural presentations happen to be complicated with distortions of the pelvis. His observations are most valuable in regard to the necessity of combined perseverance and caution, but they are too long to quote in detail. He tells us that "it has been said that children have been sometimes born alive when the strongest efforts, and those continued for many hours, have been made, to extract the head in this position, but I have not been so fortunate as to meet with any such instances, a short space of time having generally been sufficient to frustrate my hopes,

and convince me that the child was dead, though when the head has been detained a considerable time, a few cases have terminated more favourably than I could have expected, and I have been agreeably surprised with the discovery of some faint signs of life, which, by the assiduous and careful use of the common means, have been improved, and the life of the child at length perfectly recovered."

"When we have," he continues, "in vain exerted all the force which we think reasonable and proper, and which in some cases, must be more than any circumstance would be thought to require, it will be expedient to rest, for the purpose of gaining all the advantage to be attained by the compression of the head. On this account, the mother will actually suffer no more inconvenience, than would have been produced if the head had originally presented, and been locked in the pelvis. After waiting some time, we must renew our attempts to extract, and thus proceed, alternately resting, and acting with efficacy and resolution, and if the hold we may have of the body or extremities of the child does not suit, a silk handkerchief or other band may be passed round its neck, and this will be found a very handy and convenient instrument."

"It must be a *very great* disproportion," adds Dr. Denman, "between the head of the child and the pelvis, which is able to withstand this method of proceeding, if we persevere in it with prudence and steadiness; because the integuments of the head will burst, or the bones be bent inwards in an extraordinary degree, or even broken." If it fail, "It then only remains that we should lessen the head of the child, and the operation may be as easily performed in this, as in the natural presentation of the head." "But it will," he continues, "be scarcely believed, how seldom this operation is necessary under these circumstances, if we have not been in a hurry, but have acted with prudence; nor have I ever known any ill consequences follow the compression which the soft parts undergo, between the head of the child and the sides of the pelvis, if proper attention were afterwards paid to the state of the bladder and rectum."*

(*To be continued.*)

CASE OF VARICOSE ANEURISM, CURED BY LIGATURE OF THE BRACHIAL ARTERY.

By Samuel S. Dyer, Esq., Surgeon, Ringwood.

(Read before the Medical Society of King's College.)

In the middle of the night of the 9th Jan., 1848, I was called to a man, 56 years of age, who had been suffering three days with symptoms of the then prevailing epidemic—influenza. My being sent for was occasioned by a sudden aggravation of his symptoms. On my arrival, within half an hour, at his house, I found him labouring for breath, in great pain at the posterior and lower part of his chest, where small crepitation was distinctly audible; sounds elsewhere perfectly healthy. Pulse full, and bounding; skin hot; thirst and restlessness. He had shivered much on the preceding day, but used no remedies for what he considered a severe cold. I at once opened a vein in the arm, and allowed sixteen or seventeen ounces of blood to flow from a large orifice. There was no peculiarity in the bleeding, except its *freedom*, which did not of course surprise me, as it was just what I intended should occur. There was no *per saltum*,—no scarlet colour,—no evidence in short, of arterial hæmorrhage. When satisfied with the quantity taken, and relief afforded, I tied up the arm as usual, the flow of blood ceasing upon the removal of the ribbon tied around the upper arm. A brisk cathartic was administered immediately, a mustard poultice applied over the seat of pain, and potassio-tartrate of antimony, in half-grain doses, ordered to be given every two hours. In the morning I found all active symptoms relieved, and a continuance in the use of the tartar emetic soon removed every trace of inflammation.

It was not until the 11th instant, two days and a night from the time of venesection, that my attention was called to the condition of the arm, which my patient described as being *numb*, with a sense of tingling in the fingers. To confess the truth, the idea of my having cut into an artery never entered my head, and I considered this symptom must depend upon a wound of a branch of the cutaneous nerve; I therefore took but slight notice of the complaint, merely advising fomentation to pacify the man; but on my visit the next day I looked at the part for the first time, and then found a slight and circumscribed swelling at the puncture, (which was healed,) throbbing on the application of the finger, and attended with the not-to-be-mistaken whiffing sound, which (with pulsation,) ceased on firm pressure being made on the artery above. There was of course no doubt as to the nature of the case, so that I at once commenced a plan of treatment for the poor fellow's relief.

Five cases of cure by pressure, in analogous instances, reported by Mr. Tyrrell,* and others by Mr. Cooper; one case of false aneurism of the brachial artery, communicated some years since, by Mr. Salter, of Poole, to the Medico-Chirurgical Society, and which has been more recently reported in the *Provincial Medical and Surgical Journal*,† wherein (if I recollect the first communication correctly,) pressure was to have been simply used as a temporary relief, until the term of pregnancy had expired, and by that time it had effected a perfect cure; and another case wherein pressure was adopted in popliteal aneurism, which I once saw, induced me to try this palliative, or at any rate, *more mild*, plan of treatment. A compress was therefore applied over the tumour, one extending two inches up the brachial artery, and a bandage from the

* "Guy's Hospital Reports," 1835, Vol. i., page 20.
† *Provincial Medical and Surgical Journal*, Dec. 3rd, 1845.

ends of the thumb and fingers, to near the shoulder. I could not, however, give this plan a chance or possibility of success; for, after having continued it but a week, the pain in the hand and fingers remaining unabated, the weariness of inactivity, and the confinement recommended, was more than my patient would bear, and he urged upon me the necessity of some active treatment, in the hopes of more speedily resuming his accustomed occupation as a labourer in a tan-yard. I was the more ready to listen to this entreaty, from the fact of his being a member of a benefit society, and therefore drawing heavily from their funds during the time of his loss of work. I now removed the bandage and compress, and finding the skin somewhat inflamed and irritated by the pressure, ordered a soft cold poultice to be applied, and a change of this to be persevered in for two or three days. The slight inflammation had by that time entirely subsided, but the size of the tumour increased in the mean time, and extended to either side, apparently between the artery and the vein, which latter was enlarged and varicose, over and above the bend of the elbow; arterial pulsation small and weak below that point down to the wrist, and, on comparison with the opposite limb; much stronger above.

An operation was decided upon, which I performed on the 27th, in the presence, and with the assistance, of my father and Mr. Westcott, by making an incision two inches in length on the inner side of the basilic vein, keeping this vessel outwards, and dissecting cautiously down to the sheath; having the median nerve held to the inner side, I passed the aneurism needle from within outwards, about an inch and a half above the situation of my former puncture. On tightening the ligature all pulsation in the tumour and at the wrist ceased. The edges of the wound were brought together with strapping, a flannel bandage was applied, and the man sent to bed.

On visiting him in the evening we found that he had felt faint once, but not to actual syncope; he complained of pain in the wound, extending some distance up and down the arm; pulse 85 in the left arm, none to be felt in the right; temperature of the two limbs much the same,—both warm and moist. Ordered low diet. No opiate.

28th. Had no sleep; suffered much through the night with pain in the arm, which has now somewhat subsided; no headache nor other constitutional suffering; slight pulsation in the lower third of the right radial artery. I removed the bandage, and merely enveloped the limb in loose flannel, to keep up the warmth.

29th. Has passed a much better night, having slept soundly at intervals; nearly free from pain, but the hand feels numb; pulsation of the right radial artery still faint and weak at the wrist. On removing the dressings I found that the wound had healed by the first intention at each end to the extent of half an inch, the other part discharging healthy pus. The situation of the varicose aneurism was occupied by a firm resisting tumour, about the size of a broad bean; no pulsation whatever, nor impulse given it by arterial action. Re-apply strapping and flannel.

February 1st. There is greater pain, of a throbbing character, about the upper arm, which is inflamed, swollen, and feels hard and tense, somewhat of the *boggy* feel given by phlegmonous erysipelas; there is very little discharge from the wound. To take a cathartic powder directly, and foment the arm continually.

2nd. Better in every respect; pain in the head gone; arm less swollen; wound discharging laudable pus.

5th. Progressively and rapidly improving; general health good; eats, drinks, and sleeps well; sits up all day, with the arm at rest, and slightly flexed. He considers the condition of the limb to be considerably better than it was prior to the operation.

16th. Wound healed except where the ligature hangs from it; this is still firm; general health continues good; walks out every day; there is no trace of the aneurismal tumour.

21st. The ligature did not come away until this morning, the twenty-fifth day from the operation, a drop or two of blood followed its removal from the wound; strength of limb rapidly increasing.

29th. Has considered himself a convalescent for the past week; no difference in the size or muscular condition of the two arms; pulse in the right weaker than in the left; in the former the posterior radial and ulnar recurrents can be distinctly felt pulsating strongly around either side of the elbow-joint. Purposes returning to his work next week.

It may appear somewhat strange that I should have acted in this case in a manner different to that recommended by my esteemed teacher on such subjects, Professor Fergusson, who, for very good and sufficient reasons, recommends in his "Practical Surgery," and also teaches in his lectures, that ligatures, in such cases, should be applied directly above and below the communication between artery and vein; but it was so difficult in the present instance to detect any pulsation *below*, that I thought it probable the division into the radial and ulnar was just at this point, and would in no small degree complicate the operation; or else that the main trunk had so diminished in size from want of passage of blood through it, as to lessen the chances of a return of the disease, from a retrocession of the blood into and through that part. Seeing, too, that the Coopers* and Allan† thought, and proclaimed to the world, that a ligature above would suffice, I was led to adopt this easier method, trusting that the case recorded by Mr. Fergusson might have been but one out of many thus failing, and that the one under consideration might be successfully treated after the manner recommended by Allan, whose words I now borrow, as I did his ideas before the operation:—

"In performing the operation for false brachial aneurism, it has been customary to open the tumour, to clear away the blood, to search for the wound in the artery, then to separate the nerve, and otherwise insulate the vessel at its wounded point; and, lastly, to apply

* S. Cooper's Surgical Dictionary; Article *Aneurism*.—Sir Astley Cooper's Lectures, *Lancet*, Vol. i, page 385.
† System of Surgery.

two ligatures, one above and one below the wound. Although the operation has been usually performed in this manner, the improved method of operating by taking up the artery at some distance above the tumour, and leaving the sac untouched, is equally applicable here, and for the following reasons is undoubtedly the preferable operation :—It sometimes happens, that by the impaction of the blood, the artery, the vein, and the nerve are so knotted together by inflammation, that they form a very confused mass, which, if it is possible to unravel, can only be done after a very tedious and painful dissection. In such a case there is great risk of including the nerve in the ligature. When the parts cannot be separated, it has been the usual practice to take a sharp surgical needle, armed with a ligature, to pass it under this thickened mass, and to tie it, including the artery, vein, and nerve. This occasions excruciating pain at the time, and the consequences are—1st, that the ligature obliterates, and makes its way through, the artery and vein, but cannot destroy the nerve, which resists the ligature; and therefore, if this be well waxed, it will keep its hold for weeks and months, and will not be removed till it either rots, or is cut from the nerve: 2nd, great tension and pain will ensue, accompanied by high inflammation and profuse fœtid suppuration; the inflammation, which is generally of the erysipelatous kind, undermines the cellular substance of the arm, lasting for months; and, 3rd, there is great risk of the thumb, fore and middle fingers,—to which the radial nerve is finally distributed,—remaining contracted and powerless. Again, even in the most favourable circumstances, the surgeon requires to make a large incision, involving the whole of the tumour; there is difficulty in getting out the clots of blood to reach the artery; it is long before the operation is finished, and afterwards there is some risk of the sac suppurating. Considering all these circumstances, I am decidedly of opinion, that the common operation should be abandoned, that the sac should not be opened, but that the artery should be tied two or three inches above its wounded point. This method was practised by success by Anel, and has been repeated with the same success by succeeding surgeons."—*Allan's Surgery*, Vol. 2, p. 359.

To save the necessity of a reference to the lectures of Sir Astley Cooper, I may also quote here the opinion he gives at the place I have alluded to above :—

"When an aneurismal tumour at the bend of the arm has been thus formed, (by venesection,) let me recommend you not to cut down upon it in order to secure the vessel; rather tie the brachial artery at the middle of the arm, and do not make an incision upon the swelling at the bend of the elbow; to put a ligature upon the vessel here is difficult, tedious, and dangerous, on account of the extravasated blood." He then gives a case which occurred at the hospital, and says,—"At the end of a week one of the surgeons deemed it prudent to secure the vessel, and he did so at the part where the wound in bleeding had been made; the operation took an hour in performing, and it was excessively difficult to find the vessel. On the following day there was much irritation and inflammation, and on the tenth day he died."

I would also refer you to a case reported in the *Provincial Medical and Surgical Journal** by Mr. Nesbitt, of Yeovil, who states that he was once present when a young gentleman punctured the brachial artery in bleeding: he stopped the hæmorrhage by the application of a tourniquet in the middle of the arm, and pressure on the veins two or three inches below the wound, whilst he proceeded to cut down on the artery at the wounded point, intending to apply a ligature above and below the opening. He now very candidly and graphically describes the difficulties he encountered :—"All the tissues were, however, so injected with blood, that I found it scarcely possible to discriminate one from the other." * * * "In this way from thirty to forty minutes had elapsed before I came to what I believed to be the artery; I loosened the screw of the upper tourniquet, and finally removed all pressure, but there was no pulsation, neither was there any hæmorrhage; the tourniquet was re-applied, and I again searched for the artery, and tied something, which I feel persuaded was not the artery." Mr. Nesbitt attributes the cure of this case (which was perfect,) to pressure above and below.

There are many circumstances which combine to make the foregoing a case of interest and importance to the practical surgeon, more especially to the younger members of the profession, and it was this idea which mainly prompted me to send a report of it for the consideration of the members of the Kings's College Medical Society.

Some degree of interest is given by its rarity, for it is seldom we see or hear a case reported; indeed this form of aneurism was not noticed at all until the time of Hunter, who, about eighty years ago, first wrote on such an inquiry. This certainly is no proof of its not having previously occurred, but it eluded the observations of those writers who have handed down to *our* days the practice and principles of their own. This accident may be produced in any part of the body where a vein is situated directly over an artery; but for reasons which must be clear enough to every one, it is more common at the bend of the elbow than elsewhere. In the greater number of instances we are told that the coats of the artery and vein become so intimately connected that the blood passes directly from one to the other; in such a case but little or no interference is required on the surgeon's part, as the limb is generally, simply a little weaker, and this the only inconvenience, since the blood which *does* pass unnaturally out of the artery, is still held in the circulating system. This is the state of things called *aneurismal varix*, but for three reasons I am persuaded that in the case I have just reported to you, it was not simply this,—1st, the tumour was too large and resisting, to be occasioned by a dilatation of the vein, and increased laterally to so great an extent, without a

* 1845. Vol. ii, No. 38.

corresponding increase in the vein above and below; 2ndly, pressure on the artery above, though it lessened, did not wholly obliterate this swelling; 3rdly, from the resisting nature of part of this enlargement, I was inclined to think there was a coagulum in the areolar tissue between the two vessels, which coagulum could not exist if the blood was in constant motion. This is the condition called *varicose aneurism*: it is in this collection between the two vessels, that the distinction consists.

Another point of interest in such a case is afforded by the fact, (and an unfortunate one it is,) that in nine-tenths of such cases a member of the profession has been the unintentional cause of the complaint; and I would now take the liberty of urging upon those who hear this case, the absolute necessity of *caution* in performing so slight an operation as that of venesection. Remember that the accident can be avoided much easier than the aneurism can be cured; do not open the median basilic vein as I did, but choose rather the median cephalic. If the former must be opened, from any peculiarity in the case, pause one moment before using the lancet, and place your finger over the spot fixed upon for its point, to feel whether the artery (as in the present instance,) be unnaturally superficial, or out of harm's way.

The other circumstance which gives some degree of interest in this case, now that anæsthetic agents are so greatly in vogue, and which perhaps, from all I read, would render it almost unique in the surgical annals of the existing age, was the total failure of chloroform—not only failure, but (from its producing excitement,) injury and impediment in the proceeding. We might theorize and speculate as to the cause of this,—whether extreme cold prevented ready evaporation from the handkerchief,—whether the inhalation of it not being agreeable to the patient, he obstinately closed his mouth against it,—or whether idiosyncracy of constitution rendered him insensible to its excellent agency. Certainly the quantity was more than should have sufficed, the drug was good, and the means adopted for its effect, were similar to those tried by others.

STRANGULATED HERNIA: REDUCTION BY THE TAXIS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I feel it incumbent upon me to offer my unfeigned thanks to Dr. Paxton, of Rugby, for his prompt and candid confirmation of my views of the general success of the patient employment of the taxis in strangulated hernia. In truth, I felt more diffidence than I thought proper to express, in publishing my experience. It is by no means a pleasant task to impugn the prevailing practice of our brethren, and nothing but an urgent sense of duty would have impelled me to do so. Allow me, however, to say, that hospital practice in hernia is too generally attended with peculiar difficulties. Before the admission of the patient the taxis has often been repeatedly tried, and the case has become complicated with symptoms of inflammation or approaching gangrene, and in these circumstances I should be the last to condemn a reluctant operation. The forlorn hope may justify it. But as regards recent cases, (often rendered eventually hopeless by injudicious manipulation,) I do believe that the efficiency of the taxis, rightly performed, cannot be too frequently urged upon the profession.

Perhaps an illustrative case or two may produce more impression than reiterated precepts.

CASE I.—My attention was first awakened to the right use of the taxis many years ago. I was called to a case of inguinal hernia in a robust, vigorous boy, about two years of age, a farmer's son. The hernial tumour had been discovered about thirty hours, but how much longer it had existed could not be ascertained. Having tried the taxis about twenty minutes without success, I began to think seriously of the operation; but the child was strong, and unusually obstreperous. I reflected that at a lone farm-house I should find much difficulty in getting the child effectually controlled, and having then no assistant, and there being no surgical assistance at hand, I confess the difficulties attending so delicate an operation began to assume a formidable character. I therefore reflected, that as no signs of inflammation were present, and the case was favourable for reduction, it *ought* to be reduced, and accordingly I resolved that it should be done,—and allow me to add, that in such a case *resolution* is half the battle. I placed the patient on a table, with a mattress and pillow, of convenient height, on his back, with his legs bent, and the limb of the affected side directed over the other, and taking my seat on a high chair, so as to command the best use of my arms and hands, I commenced, steady, gentle, and gradually increasing pressure on all sides of the tumour, and *in an hour and three quarters*, just as my strength was beginning to fail, I had the satisfaction of perceiving an evident decrease in its size, and in a few minutes heard the gurgling noise which preceded its return into the abdomen.

CASE II.—About two years ago, I was called late at night to a case of strangulated inguinal hernia, in a carpenter, aged 60, who had formerly worn a truss, but having broken the spring, believed the rupture cured. The tumour had existed fourteen hours; it filled and distended the scrotum; it was twenty-five inches in circumference, and of course could only be partially covered by both my hands; it was tender, as well as the abdomen; and nausea, quick pulse, and sunken features, proclaimed the urgency of the case. The patient was laid on his back in bed, the muscles relaxed, and placing myself on my knees, supported by a pillow, I compressed the tumour with both hands, as one might squeeze a mop. In half an hour my hands were both paralysed, and no apparent result obtained. I then sent for my assistant, who took my place; meanwhile I supplied myself with O'Beirn's defæcation tube, as the next best resourse, if the taxis should fail, and also some tartar-emetic. My assistant was tired in his turn; I resumed my laborious post, and in two hours from the commencement of the pressure, the tumour was evidently softer and smaller.

The reduction was soon afterwards accomplished, and the patient had not one bad symptom.

I have selected these two cases from a large number as illustrative of the method, and can add nothing in favour of its success more convincing than the results. I trust many members of the Association have met with similar cases, and I entreat them to come forward and support a mode of treatment which I think no honest intelligent surgeon can condemn.

I am, Sir, yours faithfully and obliged,

THOMAS HUNT.

Herne Bay, March 14, 1848.

THE TAXIS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

On Saturday, the 12th of February last, I was reading Mr. Hunt's letter, dated Herne Bay, December 18th, 1847, "On the Taxis in Strangulated Hernia," and before I had finished it I was sent for to a most alarming case of strangulated hernia, in a woman, of the name of Sarah Mapp, about seventy years old, of Clow's Top, about five miles distant from this town. The descent, which was on the left side, took place on the previous Tuesday, while she was opening a door which required some exertion. As was usual with her, when it descended and became painful, she placed herself in the proper recumbent posture, and always, till now, effected the reduction. The first descent occurred nearly twenty years ago, at or about her last labour. She was now foiled, for the probability is, that the incarceration commenced at the moment of its descent. The excruciating pains about the præcordia, and strictured parts, the sickness, and vomiting, soon induced her to send for me that day. I found her in great agony, the hernia very hard and painful, with constant sickness and vomiting, tenderness of the whole abdomen, peculiar pain and constriction about the diaphragm and stomach, and costiveness. The hernia would hardly bear the least pressure; however, I tried the taxis ineffectually for nearly two hours, with my patient in the most favourable position. I gave her opium and calomel, with the saline camphorated mixture.

In the morning I saw her again; the same train of symptoms existed, with hiccup in addition, all the day; and on the following morning I proposed the operation by the knife, and that Mr. Davis, of Tenbury, should meet me that evening, or early the next morning. This was not agreed to, and two gentlemen were sent for from Bewdley, on Friday, without my knowledge. They tried the taxis for upwards of two hours, using, as the patient and attendants informed me, very great force, so that her groans and shrieks were truly terrific. All their efforts, however, to relieve her proved unavailing, and they left her, consigning her to inevitable death in two or three days at farthest, unless the knife was resorted to, and to this she declared she would never consent.

On Saturday I was again summoned to her, while I was reading Mr. Hunt's letter, which made so forcible an impression on me, that after re-reading it, I hastened to my patient, persuaded of the true philosophy of Mr. Hunt's reasoning, as it explained to me why I had succeeded in a case which was fresh in my recollection, and which I will advert to presently. On reaching the house I found the woman with every symptom aggravated, and the abdomen very tympanitic, and every appearance of the near approach of mortification, which I concluded was inevitable, particularly on hearing of the force employed the day before. The hernia was so exquisitely tender, that I had the greatest difficulty to persuade her to permit me even to touch it; at last I prevailed, and commenced very gently, "not by pushing, and kneading, and thumbing, but by gentle equable compression on all sides of the tumour, the abdominal and psoas muscles being previously relaxed," so as gradually to empty the distended veins; and I was determined to proceed, confident of effecting the return of the contents of the sac, though I had every reason to anticipate mortification, as before observed. After the lapse of an hour and a half, she ceased moaning; the sickness and hiccup abated, and the hernia was softer, and soon after I felt a motion in it, and in another hour reduction was affected. I now administered an enema, which went up easily, and remained about five minutes, and returned uncoloured, but before half an hour she had three large fæculent motions, with a considerable discharge of flatus.

It would occasion unnecessary waste of your valuable space, if I were to detail the subsequent treatment, which was very simple; suffice it to say, that the hiccup and sickness soon entirely left her, but the abdominal tenderness remained about a fortnight, and she is now restored to her usual state.

The case to which I promised to advert is the following:—

Mrs. Wheeler, an inhabitant of this town, died about two years ago, in her 93rd year. She was a patient of mine about 30 years, and was subject to a femoral hernia exactly similar to Mrs. Mapp's, during the whole time, except that she frequently required my assistance. Owing to her negligence in the use of her truss, and some peculiarity, the hernia was often incarcerated, and she had considerable difficulty in reducing it herself, and would frequently postpone calling me in, till pain and sickness compelled her, which was two, three, and sometimes four times a year. Before effecting reduction by the taxis, two hours' constant, gentle, and equable pressure were always required, and I invariably observed a motion in the tumour some time prior.

I have seen in subjects of different ages, and sometimes in young boys, very serious cases of paraphymosis, but I never met with one irreducible, by adopting the means recommended by Mr. Hunt in the taxis. In these cases we know that it is by gentle and steady pressure of the glans, so as to evacuate its blood-vessels, that the favourable result is accomplished.

I remain, Sir, yours respectfully,

THOMAS POPE.

Cleobury Mortimer, March 17, 1848.

Hospital Reports.

LOWESTOFT INFIRMARY.

SURGICAL CASES, UNDER THE CARE OF W. C. WORTHINGTON, ESQ., F.R.C.S, SENIOR SURGEON TO THE INFIRMARY.

Case I.

REMOVAL OF A PORTION OF THE TONGUE BY LIGATURE.

Elizabeth Townrow, aged 43, was first admitted an out-patient, about five months since, suffering form an ulcer, situated on the left border of the tongue, extending towards its base. Notwithstanding the employment of arsenic, iodine, sarsaparilla, and mercurials, together with the removal of every source of local irritation, the disease increased. The ulcer, which at first was not much larger than a split pea, and superficial, now occupied a surface of at least an inch in length, and half an inch in breadth. In the centre was a deep slough, irregular, and excavated, the surface here and there dotted with bright granulations; the margins of the ulcer were hard, inelastic, and slightly puckered.

The sublingual glands being unaffected, and her general health good, my colleagues agreed with me as to the expediency of no longer trusting to constitutional treatment, but proceed at once to the removal of the diseased portion, by means of ligature. The tongue being secured by aid of a towel, a needle, fixed in a handle, with a perforation at the point, such as recommended by the late Mr. Liston, was employed for the purpose. This was armed with a double ligature, and passed midway behind the ulcer; a second was passed at the point next the base. These were securely tied, so as completely to isolate the whole of the diseased portion, the tongue being previously notched at the extreme ends of the ulcer, for the purpose of more easily and effectually fixing the ligatures.

Very little swelling followed; a degree of salivation ensued; and on the seventh day from the operation, the strangulated portion became detached; since, little or no pain has been experienced; the surface of the wound presents a healthy aspect, and is rapidly healing.

Case II.

MALIGNANT ENCANTHUS REMOVED BY EXCISION, FOLLOWED BY THE APPLICATION OF THE ACTUAL CAUTERY.

Malignant encanthus is described as being by no means a common form of disease. Mr. Guthrie asserts in his work on "Ophthalmic Surgery" never to have seen inflammation of the caruncula lachrymalis assume a scirrhous or cancerous condition. Scarpa appears to have been well acquainted with its nature, and has favoured us with the best description. Mr. Liston and other authors have only cursorily alluded to the subject, and recommend excision; but in spite of all, it is remarked, the disease will frequently re-appear.

In the present case the operation had been performed four or five times, but notwithstanding the incisions had been carried deep in the angle of the eye, and close to the lachrymal bone, the excrescence sooner or later returned.

Three months have elapsed since the last operation; it is now the size of a large walnut, involving the whole of the caruncula, the surface assuming a mulberry appearance, which bleeds upon the slightest touch. Its base has encroached considerably on the conjunctiva, but the cornea remains intact. Both eyelids are everted, and the whole of the eye-ball is covered with the excrescence. The patient, a female, was again urgent for its removal.

Simple incision having before proved unsuccessful, it was proposed, in addition to the above means, to apply the actual cautery, in hope of insuring a more satisfactory result.

It is unnecessary to describe the preliminary steps of the operation, which were much the same as noticed in a former number of the Journal, the only difference was, that owing to the increased size of the tumor, and its attachment to the lids, it was found necessary to sacrifice a considerable portion of these appendages. The tunics of the eye being carefully protected by means of wet dossils of lint, the actual cautery was applied freely to the wound. At the end of a few days all local irritation had subsided consequent on the operation, and the patient expressed herself as having experienced a considerable palliation of symptoms.

Case III.

EXCISION OF AN ENCYSTED TUMOUR, SITUATED ON THE INNER BORDER OF THE MASSETER MUSCLE.

The case seemed to be simple enlargement of a sebaceous follicle, the swelling about the size of a pigeon's egg. The patient, a young man, about 20 years of age, described it as having existed for several years. It presented an unsightly appearance, and a desire was expressed for its removal.

A straight incision was made over the centre of the tumour, and the cyst carefully dissected out. It was found to contain a dark curdy matter. The wound healed by the first intention.

Case IV.

HYDROCELE OF THE SPERMATIC CORD TREATED BY PUNCTURE.

John Killock, aged 53, first observed a swelling at the scrotum, about four months since, which came on after violent exertion. The swelling is not large, situated above the testicle on the left side, tense, transparent, and fluctuation very perceptible. By means of a trocar and canula six ounces of attenuated clear fluid were drawn off. In this stage of the disease it was not considered advisable to inject. The patient was advised the recumbent position, and to apply a suspensary bandage.

It may be here remarked, that in Cases II. and III. the chloroform was administered by means of Coxeter's inhaler. The same success attended its employment as on former occasions.

PROVINCIAL
Medical & Surgical Journal.

WEDNESDAY, APRIL 5, 1848.

The rejection of Lord Ashley's resolutions for the improvement of the administration of medical relief under the Poor-Law, however it may be productive of disappointment, will scarcely cause surprise to those who are acquainted with the manner in which subjects of this kind are looked upon in the House of Commons. We fear that little is to be expected from our so-called representatives in any question in which the interests of the medical profession are concerned, where the Government for the time being does not lend its aid. Three divisions took place, in which the majorities against the resolutions were severally 50 to 37, 101 to 19, and 98 to 36, when Lord Ashley finding that it was useless for him to proceed further, withdrew the remaining resolutions. Seeing, therefore, how inadequately represented, or rather, how entirely unrepresented is the medical profession in the House of Commons, the appeal must now be made to Her Majesty's Government, and by a well-digested statement of facts, shewing the pressure on the medical officers, and the inefficient working of the present system as regards the poor, we hope at least to convince the minister that gross injustice is done to the one party, and much and unavoidable neglect and injury experienced by the other. We believe the present Home Secretary to be open to the reception of such a statement, and there is some encouragement also in the sentiments which were elicited in the course of the debate from Mr. Buller and Lord Ebrington. We find the chief Commissioner admitting that in many districts the salaries of the medical officers are insufficient, and that it was absolutely necessary that medical officers should receive a more adequate remuneration for their labour; and there were some other points also in which indications of more correct and enlarged views on the subject were suffered to appear.

The Home Secretary, we are glad to learn, has consented to receive a deputation from the Medical-relief Committee, and the deputation will, we understand, be supported by representatives from the Colleges of Physicians and Surgeons, the Society of Apothecaries, and from the Provincial Medical and Surgical Association. With the facts and documents in the possession of the Committee, we cannot doubt that their representations must gain the attention of the Right Honourable Baronet; and it is scarcely to be conceived that, with his eyes opened to the workings of the present system, to the contumely and neglect with which the just remonstrances of the medical officers have hitherto almost invariably been treated, to the efficient manner in which for the most part, as far as the manifold imperfections of the arrangements would admit of, they have fulfilled their engagements, to the anxious and laborious nature of their duties, to the dangers frequently encountered in the discharge of them, and to the wretchedly inadequate salaries with which their services are recompensed,—it is scarcely to be conceived that with these circumstances brought fairly before him, a gentleman of character, such as Sir George Grey undoubtedly is, can refuse to redress the grievances so deeply felt by a meritorious body of public servants like the Union Medical Officers.

In one point of view the defeat of Lord Ashley's resolutions may, indeed, work well for the medical department of Poor-Law relief; the necessity for some medical inspection seems to have been admitted by Mr. Buller, and should the further examination of the question by the Government authorities tend to deepen the impression, so as ultimately to place this department under the supervision of a qualified medical commissioner, releasing at the same time assistant-commissioners, boards of guardians, relieving officers, *et id genus omne*, from the superintendance and management of duties, the faithful discharge of which they can neither appreciate nor understand, good will ultimately work out of evil, and Lord Ashley, though now not successful, may yet witness the fulfilment of his benevolent intentions, in the consequent benefit of the sick poor on even a more extended scale than he had before felt himself warranted in anticipating.

Reviews.

On Poisons, in Relation to Medical Jurisprudence and Medicine. By Alfred S. Taylor, F.R.S., Lecturer on Medical Jurisprudence and Chemistry in Guy's Hospital. London. Fcp. 8vo., pp. 855.

The acknowledged excellence of Mr. Taylor's Manual of Medical Jurisprudence, now the text book on the

subject in this country, is in itself sufficient to cause the work before us to be received with attention; while the reputation of Mr. Taylor for his researches in toxicology and experimental chemistry, and the unhappy frequency of criminal poisoning which has of late years been brought to light, give both to the subject, and to the essay before us, an interest which a perusal of the latter will not fail to gratify.

Our readers must not be deceived into under-estimating the extent to which the subject is treated of, by regarding merely the form adopted for the work. Notwithstanding its manual-like size and appearance, it will be found to contain as much in amount of matter as might have been distributed through two or three octavo volumes. There is therefore no ground for objection that the important questions herein discussed are passed over lightly or treated superficially. On the contrary, they will be found to be entered into with sufficient detail to convey all the information, as far as hitherto known, necessary for the illustration and comprehension of the action of poisons, the modes of detecting them, and the treatment to be adopted in the endeavour to obviate their effects.

The first fourteen chapters are devoted to the consideration of poisons in general, and of medical evidence in cases of poisoning. This includes the mode of action of poisons, their classification, the symptoms produced, the treatment, the rules for investigating cases, the examination after death, chemical analysis, &c., forming about one-fifth of the entire volume. In the remaining chapters the individual poisons are examined in succession, classified under the respective heads of non-metallic irritants, including mineral and organic acids, alkalies, and alkaline salts; metalloidal irritants—phosphorus chlorine, bromine, iodine, and sulphur; metallic irritants—arsenic, and the other poisonous metals and their compounds; vegetable irritants; animal irritants; narcotics; narcotico-irritants; and poisonous gases. The details in each case are full of interest and instruction, comprising a notice of the poisonous substance or agent, the symptoms produced by it in the various states or forms in which it may be administered, the quantity required to destroy life, the period at which death takes place, the treatment, the chemical analysis, &c., and illustrated throughout by notices of appropriate cases and references to judicial investigations.

The foregoing brief analysis will afford some idea of the plan of the essay, to give anything like a sufficient notice of the work is beyond our limits. That portion which relates to general poisoning, and to the medical evidence, should be carefully perused and studied by all who are liable to be called upon to investigate or treat cases of poisoning,—in other words, by every medical practitioner. That which relates more especially to the nature and action of individual poisons, will be advantageously consulted as occasion may require. In conclusion, we must briefly express our opinion of the great value of this treatise, as a guide to the medical practitioner, the medical jurist, and the barrister, in all that relates to the subject of poisoning. With Mr. Taylor's known reputation on this question, no medical witness could now venture to appear in a court of judicial inquiry without being conversant with his opinions on medico-legal subjects, and it is well that in so important a branch of these inquiries, the present work is published in such a form as to be readily accessible to all.

An account of the Cultivation and Manufacture of Tea in China. By Samuel Ball, Esq., late Inspector of Teas to the Honourable East India Company in China. Post 8vo., p. 382.

The important office held by the author of this work, under the East India Company, afforded him peculiarly advantageous opportunities for investigating the subject of teas; and the work before us is the result of his observations and enquiries. Great pains have evidently been bestowed upon the book, and it is profusely illustrated with wood-cuts and steel-engravings. The author describes minutely every process through which the leaf passes in the course of its preparation; he enters at length into the consideration of the soil and climate most suitable to the growth of the plant, and gives us full insight into its cultivation.

The characteristic colour of *black* tea is ascribed by the author to the elaboration and fermentation of a saccharine principle, the tannic acid of the leaves disappearing and being replaced by sugar, whilst the green resinous principle is replaced by reddish brown colouring matter.

Mr. Ball satisfactorily demonstrates that *green* tea owes its hue, not to copper or to chemical adulteration, but simply to manipulation. "It may be remarked, (says he,) "that it was long an established opinion in Europe, that green tea derived its grey or bluish appearance from being dried on copper. The preceding accounts demonstrate that such an opinion is altogether unfounded. The same colour can be produced by drying the leaves in a copper vessel as I have proved by experiment; but the tea thus dried appeared to me to partake of the flavour of the vessel; and consequently, a vessel which produces a flavour so objectionable is not likely to be employed. Nor does this peculiarity of colour arise from any metallic influence of the vessel in which the leaves are roasted, for I found by experiment, that the same bloom-like colour could be produced in an earthen vessel."

Our space does not permit of our entering more fully into the merits of this work, but we can cordially recommend it as containing much curious and valuable information, and many hints that may be of service to the medical practitioner.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

ON THE USE OF COTTON WOOL IN BURNS AND SCALDS.

By John Chhistopher Davie, Esq., Surgeon, Haddenham.

I cannot but think the recorded opinions of so many able contributors upon the treatment of burns and scalds which our Journal has teemed with, are likely to be attended with great benefit. It will thus be perceived in what manner each gentleman's practice differs from another, and in this department of surgery I consider efficiency does not altogether depend upon the remedy, but upon its particular applicability, so that a large number of facts being thus collated, inferences may be drawn which will ultimately lead to more systematic and established principles upon this—a subject so grievous, and of such frequent occurrence. In the most severe cases art avails nothing in the reparative processes; all it can do is to appease suffering; but in the less extensive, and where there is great tenacity of life, it may be of invaluable assistance, by forwarding nature's operations in her restorative powers. First, where there is only increased action of the cuticular surface, and, secondly, where the inflammable matter has been sufficiently active to produce vesication, I treat such cases upon ordinary principles. Thirdly, but where the parts are charred, and there is no hope of vitality being resuscitated, I envelope the whole of the injuries with cotton wool, retained by compress and bandage. As soon as the patient is placed in bed, a full dose of laudanum is given; during the stage of collapse, brandy, ammonia, or wine, are more or less freely administered. When re-action has commenced, stimulants are discontinued, and the system is relieved by an aperient of calomel and castor oil; afterwards, a generous and nutritious diet, of which animal food and malt liquor form a part.

The view I take of the proceedings to be adopted in burns and scalds is,—where there is a disposition to sloughing, or this deadly process has actually taken place, the parts should be entirely secluded from the air, and I am unacquainted with any application so fully capable of effecting this as a covering of cotton wool, the injuries being kept in a state of quiescence, and without unnecessary interference. The removal of dressings every day only tends to aggravate suffering, to cause the most distressing sensations, and to excite unhealthy granulations, and, I believe, is productive of inflammation and congestion of internal viscera, as well as retarding the animal powers. The separation of dead from living parts is nature's office, rather than that of art, and I think in this instance she is best served with the least possible interference.

From what I have seen of cotton wool, and the success which has attended its use in my practice, I give it a decided preference to any other remedy with which I am cognizant: It is a non-conductor of heat and cold, thereby tending to equalize the temperature of contiguous parts; it facilitates suppuration, which is much to be desired, in a measure, making up the deficit of the eliminating organs; it causes a healthy granulating wound, with an even surface, which forbids the use of caustics, and other external stimuli; and where the abrasion has not been very extensive, the new formed skin is smooth and without those rugged cicatrices which are too often perceptible.

The manner I employ the cotton is as follows:—The whole of the affected parts are superimposed by very thin and finely pulled layers; then layer upon layer is applied, until a thick coating is formed, which is secured by compresses and bandage; the latter appendages should be carefully removed every day. This soft texture soon becomes caked, which I encourage as much as possible, so that it may form a casement, which should remain unmolested for days together, and which will tend to forward and complete the cure in the most perfect manner the exigencies of the case will admit of. Upon the length of time the wool is allowed to remain upon the surface of the wound, in my opinion rests its claim to superiority: if removed daily its object is completely frustrated. If there be exudation of matter, it is to be removed; if the effluvia be offensive, the dressings are to be saturated by the usual lotion of chloride of lime, and should any part of the wound be bare, a fresh piece of wool is to be added to it. I have frequently observed the healing process advanced to some extent before the sphacelus had been entirely detached, where the textures had been thus protected. The dressings having been retained *in situ* as far as compatible with circumstances, the greatest care should be taken upon their removal; they should be well soaked with warm water, small portions dislodged, which should be immediately renewed by the like substance. This operation I do not find necessary to be repeated oftener than once in eight or nine days, sometimes longer, which by this undisturbed state of things, is a very great saving of time to the attendant, and of suffering to the patient. The two following cases are illustrations of the employment of cotton wool:—

Case I.—November 24th, 1843, James Thurlow, aged 4 years, of Haddenham, had the integuments destroyed covering the entire surface of the scapulæ; the right axilla; the circumference of the upper part of the humerus, the whole of the posterior and lateral parts of the same extremity, taking the course of the triceps muscle, and extending some way from the olecranon process; large detached portions on the right side of the thorax, and the top of the abdomen; the entire surface of the ilium, inguinal region, and upper-third of the thigh of the same side. The plan which I have before described was adopted; the lower arm was bent, and the recumbent posture strictly enjoined. When the cicatrization had commenced, the affected joints were fully exercised every day, with due regard to the dressing being in exact apposition. Some weeks after he had an attack of scarlatina, and the only wound then unhealed was that over the ilium, and the adjacent parts, which became irritable, and its action very unhealthy, so that it was impracticable to continue the adhibition of the cotton wool any longer. During this state of excitement of the system, the wound was dressed with lint and warm water, afterwards with an ointment composed of bees' wax and linseed oil, with the occasional application of potassa fusa, and the cure was effected March 13th, 1844. He has the free and perfect use of the right upper and lower extremities; the skin over the shoulder blades, axilla, side, upper and lower arm, is smooth and without the usual contraction after such accidents; but the cuticular surface in the inguinal region is puckered, though mobility of the extremity below is not at all restricted.

In this class of cases, where there are exuberant granulations, I prefer the potassa fusa to any other caustic. In some instances which I have witnessed after the medical practitioner had been dismissed, the cicatrized parts were attended with much pain and irritation, in consequence of the surface being above the natural skin, and the only remedy from which relief could be found, was the free application of the potassa fusa.

Case II.—February 25th, 1845, my attendance was requested upon Ann Croxen, aged 8 years, of Aldreth, a hamlet of this parish, who had been severely burnt, comprising the entire of the exterior of the front and lateral parts of the neck, together with the under part of the lower jaw; the right and left axillæ; the posterior and lateral parts of the right and left upper arm, along their whole extent; the right and left scapulæ, with the intermediate integument of the back, and the undivided lateral parts of the chest. She was submitted to the same plan of treatment as in the other case. After three months of unremitting assiduity on my part, I resigned it to the care of the parents, at which time the wounds of the right and left chest, left scapula, axilla, and arm, were well; cicatrization was somewhat advanced over the right scapula, axilla, and upper arm, but the remaining part of the case did not go on so prosperously as heretofore, which I consider to have arisen from motion of this extremity not having been enforced, and the dressings not being in co-aptation. In consequence of the latter, the wound lost its healthy action. Unguents were employed, and ultimately this part of the cure was effected, but much less perfectly than in those parts wholly treated by the cotton wool. I may here be permitted to remark, that in the like cases, where cotton has been misused, and the abrasion has been some time in existence, I have never been enabled to employ it with the same advantage as in the early stages. The present condition of the child is the following:—She has the free and unrestrained motion of the left shoulder; the new-formed skin, and that of the axilla, is smooth and pliable; the chin is not at all depressed, and she has the free motion of the mouth, but the skin over each sterno-cleido-mastoideus muscle is puckered; the exterior of the left side is smooth. Mobility of the right arm is less perfect than that of its fellow, though she can raise the arm as high as the head; it is restricted by a band of integument, from the side to the upper arm. I do not remember ever having before seen a burn of such extent, and involving such important parts, recover; yet, contrary to expectation, there was scarcely a militating circumstance which impeded the successful result of the case. In the diarrhœa following burns which might be supposed to arise from suppression of a discharge to which the constitution has become naturalized, I have found the sulphate of copper and opium most invaluable.

I travelled 16½ miles to this case, and my time was occupied a greater number of hours in attending to it, for which I received nothing more than my annual salary for general illness. I pray that in the new Medical-relief regulations, burns may be one of the extra-charges.

Haddenham, March 4, 1848.

COMMUNICATIONS.

[The following communications have been forwarded by Mr. Crompton.]

From Henry Wilkinson, Esq., Surgeon, Rotherham.

There is no subject connected with medicine or surgery on which there is more diversity of opinion than the treatment of burns. During my apprenticeship, and for some time after commencing practice on my own account, we used to treat all cases by the Kentish or stimulant method. But often observing that the patient suffered severe pain, as the consequence of this treatment, besides meeting with many intractable sores, I began to think that the principle or theory of such practice was not sound; and on reflecting that the skin was a highly sensitive and vascular organ, and that when inflamed by fire or other stimuli, its sensibility was increased, I came to the conclusion that a more rational method of treating these accidents might be arrived at, during the first or inflammatory stage in particular, by which method we might lessen considerably the morbid sensibility of the parts, and consequently the suffering of the patient, whilst at the same time we diminish the liability to a tedious, debilitating, and intractable sore. With these impressions I decided on the trial of cotton wool, along with such other remedies as were most likely to allay pain and irritation, which plan proving so successful in my hands, I have continued to follow it up to the present time, so that whenever I am called to a burn or scald, whether superficial or deep, slight or extensive, I first smear the parts over freely with a liniment, composed of equal parts of Oleum Lini and Aqua Calcis, with about two drachms of Liquor Plumbi Acetatis to the pint; afterwards I cover them effectually with cotton wool, which is very easy of application, and may be retained without difficulty. The patient will generally experience relief from pain immediately, and this first dressing I allow to remain until it can be easily removed by the exhalation from the skin, or the desquamation of the cuticle itself, (for we frequently find in extensive burns, that we have every degree of injury, from a simple scorch to the complete destruction of the substance of the skin;) I therefore remove the wool piece-meal, according as it may be set at liberty by the discharge, or become offensive, and I only re-apply it after the same manner to such parts as may have to slough, and merely require a covering whilst nature is performing that process, so that the wool is only made use of as a means of protection to the highly sensitive surface, preventing access of atmospheric air, and, being a bad conductor,* assisting the animal heat in promoting suppuration.

The next step to be considered is that of checking the tendency to inordinate discharge, a striking feature in such cases. For this purpose I generally use some absorbent powder, such as chalk or calamine; or if these should be found to irritate, (which they seldom do,) I

* Mr. Wilkinson has written to me to say that his paper was written before he received the last number of the Journal, in which there is a foot note, at page 155, respecting most remedies in burns being either *non*-conductors of heat, or what the old writers called *calorifacients*. He observes, "You must not imagine that the idea was borrowed from perusing that Journal. It was singular enough that my assistant, Mr. Dixon, who had read my original copy whilst I transcribed it, happened to take up the Journal when I had the letters sealed up for you in my pocket, and he being struck with the similitude of some of the remarks, called my attention to them."—(S. C.)

substitute flour, dusting the sore over with one of them previous to an application of wax, lead plaster, olive oil, and calamine, in such proportions as to form a very firm cerate. This cerate I invariably use as a covering to promote the cicatrization of all granulating sores resulting from burns or scalds, having found it the best sedative application for keeping down irritation in the sore or surrounding parts. But as the granulations in these ulcers have a great tendency to become fungoid, I find it necessary to apply an escharotic; and for this purpose I know of nothing better than brushing them over with a solution of nitrate of silver, (about a scruple to an ounce of water,) with dry lint to the most prominent points, supporting the dressings with bandages on all such parts as will admit of them, as moderate pressure will always have the effect of assisting the healing process.

The next thing to be considered is the constitutional treatment, which is of so much importance in all serious burns, and this, of course, will be regulated by the discretion of the practitioner. As far as my experience goes, I find opium a most valuable auxiliary, during the inflammatory stage in particular, giving it in proportion to the amount of pain or constitutional irritation the patient may suffer. Aperients are also useful during the early stage, inasmuch as they reduce morbid or excessive heat, and act as revulsives to the skin; but when the suppuration stage has once set in, they cannot be too carefully administered, as the patient's strength might be injured thereby, a circumstance, of all things, to be guarded against, as nothing is more prejudicial to a speedy recovery than a diarrhœa, which not unfreqently comes on spontaneously when we least desire it. There are other remedies which might be mentioned,—diuretics, for instance, which counterbalance, in some measure, the loss of the functions of the skin. But these having been pointed out by Sir Astley Cooper, Mr. Earle, and others, in their lectures and treatises, it is not necessary for me to do more than allude to them. It is likewise almost needless for me to say, that when the reparative process is going on, it is proper that the patient be allowed a generous diet, with plenty of animal food; but I entertain strong doubts as to the propriety of stimulating drinks, particularly during the summer months, having frequenty found them produce uneasiness in the wounds, and prevent the patient resting. The constitutional symptoms will vary according to age, sex, and temperament, as well as situation and extent of injury. I had a case of burn some time ago, which so strikingly illustrates the two last-named modifications, that I cannot avoid alluding to it here. A boy, about ten years of age, sustained a burn of the abdomen and thighs. Within twenty-four hours tympanites, with vomiting and constipation, supervened; in short, every symptom of peritoneal inflammation. I bled him from the arm, to complete muscular relaxation. The bowels acted freely immediately, and the little patient did well, although most of the skin of the abdomen sloughed. This is the only case wherein I have opened a vein on account of a burn, but it serves to show that we must not be deterred from treating a case upon established principles, because it was the result of an uncommon cause; and it likewise appears to reverse the theory of the homœopathists, *(similia similibus curantur,)* as the external inflammation, instead of curing or preventing, actually occasioned the internal.

The preceding remarks are the result of a pretty fair field of observation and practice, holding as I do appointments to collieries where these accidents are very common, besides what may happen in union and private practice; so that if there be a branch of surgery on which I can speak with confidence, it is in the treatment of burns and scalds, as the plan I have adopted has been invariably attended with success in all cases which offered a prospect of cure. In conclusion, I must not omit to allude to the state of the cicatrices, as the result of this treatment, and the best mode of describing them, will be to say, that out of the whole number of burns which I have had to treat, I do not know of one patient with a contracted joint as a consequence of the burn. I had one case of a little girl, who had a contracted elbow in consequence of the friends undertaking to dress the wound themselves. She was brought back to me after cicatrization was complete; I divided the cicatrix with a scalpel, extended the limb on a splint until the wound healed, and the deformity did not return.

[A communication from Mr. Barrow, of Bath, is unavoidably delayed till the next number.]

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

January 6th, 1848.

James Russell, Esq., in the Chair.

FIBROUS TUMOUR OF THE UTERUS.

Dr. Russell presented a uterus, containing a small fibrous tumour, round, about one inch in diameter, situated in the fundus of the organ, embedded in its muscular coat, but projecting towards the peritoneal surface, where it was only covered by a very thin layer of the fibres of the uterus. It had been taken from a woman of middle age, mother of two children; she died from perforation of the stomach. Dr. Russell was not aware that she had ever had any symptom from which to infer the existence of the disease.

LARYNGITIS.

Dr. Russell presented a larynx, lined with soft lymph. It had been given him by Mr. Percival, with the following history, and notes of the *post-mortem* examination:—

A girl, aged 19, previously healthy, stout and muscular, was at work at pearl buttons all day on Thursday, December 23rd. On Friday she was poorly, and complained of sore-throat. She was seen by a medical man, who thought she was labouring under influenza, and treated her mildly for that complaint. On Saturday morning she was lying in bed, when she sprang up suddenly, put her hand to her throat, called out "Oh! my throat," and fell down dead.

Sectio cadaveris, thirty-six hours after death. Brain enormously congested, and unusually dense and firm, with an immense quantity of grey matter. The sinuses were full of blood; choroid plexus also congested; not an unusual quantity of serum in the ventricles. Convex surface of the right lung adhered unevenly by quite recent lymph; lungs healthy, containing only a few tubercles. Heart healthy. There was a patch of recent lymph on the peritoneal surface of the liver. Intestines healthy. *Larynx*:—The mucous membrane

was of a bright scarlet colour, extending down the trachea and large bronchi. The submucous cellular tissue of the larynx was much infiltrated, thereby narrowing the rima very much; an ulcer of the mucous membrane in the right ventricle. The epiglottis was much infiltrated, especially the tip.

In connection with this case, Dr. Percy related the history of a boatman, who suffered from hoarseness, dyspnœa in paroxysms, with tenderness under the sternum. One of the cervical vertebræ was noticed to be prominent, and there was tenderness in that spot. He died very suddenly, without any appearances being detected after death, except a small ulcer in the larynx, and a plug of muco-purulent matter in the larynx, below the rima. He had no syphilitic affection.

INDURATION OF THE PLACENTA.

Mr. Mackay brought forward a placenta, presenting at one portion of its edge a peculiar udder-like structure. The day before the labour considerable hæmorrhage occurred, continuing from six a.m. till twelve at noon; it then ceased. Labour came on in the evening of next day; it was natural, but flooding took place immediately after the birth of the child. On introducing his hand, Mr. Mackay found a portion of the placenta within reach, whence he supposed that it was removable, but as it was not easily withdrawn, on further examination he discovered that it adhered to the fundus of the uterus so firmly as to render it difficult to distinguish between the placenta and uterus. The hæmorrhage ceased at once on removal of the placenta. During the pregnancy the woman had experienced pain near the position of the adherent portion of the placenta. She had had several children, and her labours had been natural. On examining the placenta, a portion at the margin of the organ, about two inches and a half in length, and one inch broad, was of a white colour, indurated, and udder-like in character; this was the part adherent. It appeared to be the result of an inflammatory process.

Mr. Mackay also referred to another case in which hæmorrhage commenced five weeks before labour, and continued three weeks, at intervals. The recumbent position was enforced, and the discharge ceased for the last fortnight before the labour. Labour was natural. A large clot adhered to about one-third of the placenta. He had satisfied himself by the stethoscope that the placenta was situated at the fundus of the uterus, and has no doubt that hæmorrhage arose from separation of that portion of the placenta, which was afterwards seen to be covered with a clot. The patient had fallen down a day or two before hæmorrhage set in.

ABSCESS OF THE BLADDER.

Mr. Hill presented the bladder of a man, aged about 76, containing a small abscess under the peritoneal coat. He presented symptoms like those usually occasioned by calculus. He was sounded but no stone was found. His illness had lasted about eighteen months, when he gradually sank and died. He derived great benefit from copaiva. On opening the body the muscular coat of the bladder was found much thickened, and its bundles of fibres greatly hypertrophied; the mucous membrane was sound. An abscess about the size of a small hazel nut, was situated under the peritoneal coat, at the fundus of the organ; it contained healthy pus. The prostate was considerably enlarged, and its middle lobe projected somewhat into the bladder; but Mr. Hill did not consider the degree of enlargement of the prostate sufficient to account for the symptoms of obstruction. No serious obstacle was opposed to the introduction of a catheter.

DISEASED MITRAL VALVES.

Mr. Ryland exhibited a heart with the mitral valves ossified and contracted to the size of a shilling.

An unmarried female, aged 47, from the age of 7 to that of 27 had been subject to frequent attacks of acute rheumatism. Previously to the last winter she used to get on pretty well. She could not walk fast without suffering distress about the heart; she could not lie on the left side; her feet and ankles swelled in hot weather and after exercise, and she was subject to severe catarrh and bilious attacks. In January, 1847, she caught cold in a railway carriage, and had in consequence, acute bronchitis, rheumatism, and carditis. From that time the distress about the heart was much aggravated. In April following I have recorded:—great heaving impulse of the heart, loud systolic murmur, frequent palpitation and small pulse; also œdema of the legs, ascites, and hydrothorax. Urine of high specific gravity, loaded with lithates; no albumen. She was relieved by mercury. In August the dropsical symptoms became again so severe as to necessitate the use of mercury, as diuretics of every form or kind, elaterium, and other hydragogue cathartics, failed. In the beginning of December, the ascites was again so troublesome, and so much impeded the respiration, that mercury was again used. It exerted its usual powers in exciting the secretions and carrying off the fluids, but the weakness and the palpitations increased, and it was soon discontinued. The breathing became quicker, the lips bluish, the heart beat most feebly, and rendered the exertion of walking a few yards very great. She took to her bed on the 27th of December, and quietly expired on the 29th, apparently from the impossibility of the heart carrying on its work any longer. There had not been any venous regurgitation.

Sectio cadaveris, forty-nine hours after death. Body emaciated; no œdema of any external part. Lungs congested to a great degree and at one spot an apoplectic effusion as large as a hen's egg; a little fluid in each pleura. Pericardium universally adherent to the heart; heart nearly twice its natural size, the increased size being mostly due to enlargement of the cavities, the parietes being of the usual thickness, but pale and softened in texture. All the cavities except the left ventricle were distended with dark soft coagulum; the tricuspid valve was thickened and incapable of fully closing; valves of pulmonary artery healthy; the mitral valve was a rigid slit, less than an inch long, and very narrow, with bony masses projecting from the sides; the aortic valves were also diseased, they were much thickened, the edges of two of them were united all the way along, but they seemed

capable of acting in such a way as to prevent regurgitation, though they must have opposed some obstacle to the onward progress of the blood from the ventricle. The abdomen contained about two pints of reddish serum. The liver was large, much thickened at its edges, and reached low in the abdomen; there were marks of chronic inflammation on its surface, and the intestines and adjacent parietes were united to it by cellular adhesions, the remnant of some former inflammatory action. The gall-bladder contained three or four large calculi.

Foreign Department.

MEMOIR

ON COMPRESSION OF THE ABDOMINAL AORTA IN UTERINE HÆMORRHAGE.

By M. Seutin.

(Translated for the Provincial Medical and Surgical Journal.)

There is no accident which the accoucheur is called upon to witness more serious, and which requires greater promptitude of resource, than uterine hæmorrhage, whether external or internal. It is of the last importance in such a case, to apply the remedy which is at once the most ready, the most easy, and the most sure in its operation. And what means can be more efficacious under this pressing emergency than the compression of the vessel above the source of the hæmorrhage? If blood escapes from a wound of the brachial artery, we at once compress the vessel above the seat of injury, why should not the same principle of treatment be applied to uterine bleeding? Why should we not compress the ventral aorta, which from its situation in front of an unyielding bony structure, is peculiarly sdapted to the operation?

The want of precise rules for the methodical compresssion of this vessel, the silence of many writers on obstetrics regarding it, and the doubting tone in which it is alluded to by those who do mention it, afford a just view of the scientific indolence of the present age. It is nevertheless, upon the testimony of Siebold, Velpeau, Saxtorph, and others, a measure of no inconsiderable value. Some few years back, I, in common with the majority of accoucheurs, but seldom resorted to compression of the aorta, and had the misfortune on one occasiou, to see a lady sink in a few moments, whom I am now convinced might have been saved. Led away by the erroneous dicta of the great masters, I neglected the only resource which from its promptitude and facility of application could alone afford a chance of success. This case, which made a great impression on my mind at the time, led me to serious reflexion, and became the starting point of my subsequent experimentation of the potency of compression of the aorta under similar circumstances. The Maternité, and the other hospitals of the city, (Brussels,) afforded me ample opportunities of puttiug my ideas into practice, and on *every occasion* I derived an *immediate* benefit, which could not have been obtained in any other manner.

I therefore think it my duty to call the attention of obstetric practitioners to the employment of compression of the ventral aorta, to point out to them the powerful assistance which they may derive from the operation, and especially to urge upon them not to regard it as a *dernier resort*, but as the first measure to be adopted.

The characteristic effect of compression of this vessel in uterine hæmorrhage, is the moderation or instantaneous suppression of the bleeding, by offering a mechanical impediment to the passage of the blood into the uterine sinuses. An immense advantage is thus given, in allowing time for the application of other means if requisite.

In order, however, that compression of the aorta should be effective, it must be properly accomplished, and for this reason we call the reader's attention to certain anatomical considerations connected with the vessel.

The abdominal aorta, which is situated a little to the left of the vertebral column as it passes through the pillars of the diaphragm, inclines to the median line in its descent towards the sacro-vertebral protuberance. It is invested by fibro-cellular tissue, and has the vena cava on its right side. It is most readily compressed at the umbilicus, at which point the abdominal walls are most supple, and the least distant from the vessel.

For the purpose of relaxing the abdominal parietes as much as possible, the woman is to be placed on her back, with the head and shoulders raised, the thighs separated and flexed on the body. The accoucheur being placed on the left of the patient, uses his left hand to compress the vessel. The right hand being unemployed, is destined to assist in the compression, or in performing any obstetrical manœuvre which may be required. The compression is made by the fingers of the left hand, which are applied longitudinally upon the vessel, and the compression is increased if necessary by an assistant pressing upon the hand of the accoucheur with his own. The compression is to be maintained until the hæmorrhage is fairly under control, which is usually in the course of a minute or two; but it must be persevered in for a longer time when the danger has been imminent from the amount of blood lost. Instead of removing the fingers at once, one or two are be to lifted successively, and replaced, in proportion as the hæmorrhage diminishes. It is seldom necessary to continue the pressure longer than ten minutes.

By these precautions we avoid the mechanical congestion of the neighbouring viscera, which would be inseparable from the permanent and prolonged compression of an artery like the aorta, and at the same time we relieve the patient from the danger of immediate dissolution, which oftentimes could not be prevented by means more tardy in their operation, or less ready of access. Compression of the aorta is not, however, merely a temporary agent, but it is also *curative*, for it relieves that plethora of the uterus upon which its state of inertia usually depends. It is plain, therefore, that it should not, as hitherto, be regarded in the light of a *dernier resort*, but as a most invaluable resource under these appalling hæmorrhages, which are frequently met with under circumstances the least favourable to the supply of other assistance.

NOTES FROM A PRACTITIONER'S DAY BOOK.*

CONSTIPATION.

I was once consulted about an old woman who had long suffered from obstinate constipation, and was obliged to take powerful and repeated purgatives. She was now worse than usual, and complained greatly of pain in the abdomen, and of the incessant sickness which had recently supervened. She was much emaciated, and her complexion was of that sallow leaden hue which is so characteristic of malignant disease. I made a most careful examination of the abdomen, but could detect nothing like a tumour. Nevertheless, my opinion was most unfavourable: there was probably, I suspected, a carcinomatous degeneration of the coats of some portion of the intestine which was obstructing the passage. I prescribed a repeated morphia draught to allay pain and sickness, and an occasional purgative of croton oil, dissolved in castor oil. The treatment produced some amelioration; the sickness and pain abated, and the purgative brought away a small quantity of fæculent matter.

At the end of three weeks (during which she remained much in the same state,) I was one morning summoned, and found all her complaints referred to the rectum, where she experienced a sense of distension, though nothing passed when she was on the close-stool. I ordered an enema. In the evening all the symptoms continued; the orifice of the pipe had become so much clogged up with fæculent matter whenever it was introduced, that no fluid could be injected. Introducing my finger, I found the rectum occupied by a mass about the size of a large cocoa-nut, and I proceeded at once to break it up, and extract it piecemeal. It had the consistence of tough clay, requiring some force for its disintegration. Its colour was of blackish leaden character; but it had no peculiarly foul smell. For some days, hard scybalous masses passed from the bowels; but she afterwards enjoyed very good health, requiring only an occasional purgative.

ACUTE ABSCESS BETWEEN THE LIVER AND DIAPHRAGM.

A man was suffering with symptoms of acute inflammation in the right side, and a divided opinion as to its seat was entertained by the several physicians who were in attendance. The stethoscopists denied that any part of the pulmonary apparatus was affected; whilst they who took the physical signs alone into consideration, maintained that the liver was in no manner diseased. Time passed, and suppuration appeared to be established, for the inflammatory fever subsided, and a succession of rigors indicated the commencement of a hectic state. In the course of another ten days he became troubled with cough, and began to expectorate considerable quantities of purulent matter; still the stethoscopists could not understand the nature of the case. In the course of a few more days the patient died. An examination explained every thing. All were right, and all were wrong. The liver was healthy, and so was the pulmonary structure. A large cavity existed between the liver and the diaphragm, circumscribed on all sides by adhesions between these two parts. The lower portions of the lung had become adherent to the diaphragm, and an ulcerated passage through these united structures communicated between the cavity of the abscess and a bronchial tube.

* (Continued from page 161.)

General Retrospect.

ANATOMY.

CASE OF QUADRUPLE MAMMÆ.

The annexed case is the second, or third at most, of the kind, which has been placed on record:—

Ann Merriman, aged 34, was delivered of her sixth child in the South Dublin Union House. It was found that she possessed four breasts. The supernumerary mammæ are on either side above the site of the mammary glands and near the axillæ. They were distended with milk and of the size of a large goose-egg, being about one-sixth the size of the true breasts, which were largely developed. On the left side the supernumerary gland is provided with a single nipple; on the right there are two. The lacteal secretion flows abundantly from them. When the child sucks the true breast, the milk runs from the other in an inconvenient quantity.

It could not be found on enquiry, that this curious malformation had existed in the woman's family. She was in all other respects well formed.

A case of quadruple mammæ is recorded in the *Dict. des Sciences Médicales*, and a second in the *Medico-Chirurgical Transactions*, Vol. iii., Second Series, by Dr. Lee.

PATHOLOGY.

HEADACHE FROM INFLAMMATION OF THE FRONTAL SINUSES.

While a student, M. Mombert was acquainted with a friend who was attacked with a violent frontal headache, which lasted the whole day, and departed towards night, again to recur with equal severity in the morning. Several physicians had prescribed for the patient without advantage. One morning in his agony the patient rubbed his forehead with such violence with a clothes brush that he completely took the skin off, leaving a wound which remained open for a considerable time. From this period the headache entirely ceased. Instructed by this case M. Mombert treated a patient labouring under similar symptoms, by applying a blister over the frontal sinuses. The result was equally fortunate.

M. Mombert believes that this form of headache depends upon catarrhal inflammation of the frontal sinuses, and that the affection may be most readily cured by counter-irritation, either directly applied to the painful part of the head, or to the nape of the neck.—*Viertel Jahreschrift für die praktische Heilkunde.*

ON THE CAUSE OF THE SOUND CALLED "BRUIT DE DIABLE."

Every practitioner is familiar with the continuous humming sound heard in the cervical region of anæmic subjects, more particularly females, but few comparatively are induced to reflect upon the mechanism of its production. In a recent communication in which the subject is investigated, Dr. Bellingham acknowledges two distinct murmurs attendant upon the anæmic condition,—one continuous, the other intermittent; the former being venous, as was we believe first pointed out by Dr. Ogier Ward; the other arterial, and seated in

the carotids. The conditions necessary for the production of murmurs in the circulation are stated to be—

1. A certain degree of roughness in the lining membrane of the vessel.

2. A certain strength or rapidity of the blood-current.

3. A certain degree of density of the blood itself. When the three conditions are simultaneously present, the murmur will be heard in its highest intensity.

In the morbid state in which the "bruit de diable" is heard, Dr. Bellingham observes that the first condition is absent, the lining membrane of the blood-vessels preserving its natural smoothness, but the other two are present, the current being more rapid, and the density of the blood diminished, a greater amount of friction, therefore, takes place, and a murmur is produced in the arteries, of an intermittent character, occurring during the ventricular systole.

In the veins, however, the current being more feeble, some other explanation is required; and it is necessary to resort to mechanical obstruction, to acconnt for the murmur. In the case in question the sound is developed in the jugular vein, as may be readily ascertained. In order that friction, sufficient to develop the sound, should ocour, Dr. Bellingham conceives it to be essential that the platysma and cervical fascia should have a certain degree of tension, which can be effected by turning the patient's head, so as to put the side of the neck examined upon the stretch. If a certain degree of pressure be now made by the stethoscope, so as to diminish the calibre of the vessel, a murmur will be developed, and will be continuous, because the venous current is continuous. If the pressure be carried beyond a certain point, so as to disturb the blood-current, the sound ceases. Dr. Bellingham is, therefore, of opinion, that there is really no abnormal sound in the vein, but that it is due solely to the pressure exercised by the stethoscope.

[He omits to add that the blood is in a state more readily to be thrown into vibrations. In a healthy subject the murmur cannot be developed by any amount of pressure. There is nothing new in the explanation of the production of the sound by the pressure of the instrument. The novelty, in Dr. Bellingham's views, consists in the part he assigns to the tensive action of the platysma and cervical fascia, as explanatory of the many anomalies attendant upon the existence of the murmur,—such as the variety of intonation, its disappearance one day, and re-appearance the next, &c., all which may, according to him, be ascribed to the accidental degrees of tension to which these structures are submitted by the posture of the patient.

In a discussion to which the enunciation of these views gave rise, Dr. Benson differed from Dr. Bellingham, in not attributing so much to the effect of pressure by the stethoscope. Dr. Byrne mentioned as a practical fact, that anæmic females, in whom this murmur was observed, were not predisposed to phthisis. This view is corroborative of what we had considered as a fanciful theory advanced by Trousseau,—that it is unsafe to cure chlorosis, as the chlorotic and tubercular cachexiæ are antagonistic, and by removing the one, we often lead to the induction of the other. Our own experience is directly opposed both to the one and the other statement; we have continually met with the anæmic venous bruit in persons in whom the presence of advanced phthisis was undoubted.]

IRRITABLE BLADDER FROM TAPEWORM.

The following case is reported by Mr. Tuffnell:—A man, of temperate habits, complained of excessive irritability of the bladder, with difficult micturition. His health had been good till three months previously, when he began to suffer from the usual symptoms of dyspepsia, with irritation of the rectum, and hæmorrhoids. These symptoms increased, and to them were added tenesmus and frequent calls to make water, which was voided in a twisted jet, and accompanied by severe straining, but no pain. He received temporary relief from taking opium; but he became emaciated, and his health had suffered severely before he applied for medical assistance. A small bougie when introduced was arrested, and grasped tightly by a stricture at the membranous portion of the urethra, the probable result of an attack of gonorrhœa, from which he had suffered some years before. The urine was highly acid, and loaded with lithate of ammonia. The prostate was of natural size, but very sensitive to the touch. The patient was ordered to rest in the recumbent position, to have a pint of tepid water injected up the rectum night and morning to relieve local irritation, and to take infusion of calumba with tincture of hyoscyamus, and liquor potassæ, the bowels at the same time to be evacuated by castor oil. Under this treatment he improved so rapidly that he resumed his usual habits at the expiration of a week. His symptoms, however, immediately recurred, and were as immediately relieved by his resuming his former treatment, with the horizontal posture. A second speedy recovery was effected, but he returned in a few days suffering severely, and anxiously desiring an operation for his relief, being convinced that he suffered from urinary calculus. The irritation about the anus had now greatly increased, and he was observed at the same time to be frequently rubbing his nose, which suggested the idea of the possible presence of worms in the intestines. A purgative of turpentine and castor oil was accordingly administered, and the following morning a tapeworm measuring thirty feet was evacuated. All the former symptoms immediately subsided, the urine became clear and healthy, and the patient was soon restored to permanent health.—*Dublin Med. Press*, Febr.

SURGERY.

DIAGNOSIS OF FRACTURE OF THE NECK OF THE FEMUR.

Mr. Bransby Cooper has the following remarks on this subject:—

The history of the case may furnish strong presumptive evidence; as, for instance, if a slight blow has produced entire loss of the limb in an old person, the patient should be placed on a hard bed on his back, care being taken that the anterior superior spinous processes of the ileum are in the same plane, when it will be observed that the affected limb is shortened to

an extent depending upon the length of time which has elapsed since the injury. The limb is also everted, so that the heel is raised above the internal malleolus of the opposite limb.

But even with these characteristic marks, a surgeon should hesitate in forming a diagnosis at once, as all the symptoms mentioned may result from dislocation of the femur upon the pubis. The grand distinguishing mark, however, is the facility with which the surgeon can, by a slight extending force, bring the fractured limb to the same length as the sound one, while in dislocation it is so fixed that no force less than that which will reduce the dislocation will produce a like effect. While the extension is maintained, the surgeon should place his hand on the trochanter major of the affected side, at the same time that an assistant rotates the limb; this will produce a sensation of crepitation. A further diagnostic mark may be obtained by the surgeon placing a hand on either trochanter major, while both limbs are rotated simultaneously; it will then be perceived that the trochanters move in arcs of different circles; besides this, it is almost impossible for the patient to raise himself in bed into a sitting posture, in consequence of the thigh bone having lost its *point d'appui* in the acetabulum. The diagnostic marks of the accident are indeed scarcely to be mistaken, and as they are also generally concomitant, there is but little difficulty in establishing a diagnosis.—*Medical Gazette,* March 3, 1848.

ON THE TREATMENT OF PENDULOUS TUMOURS.

By Dr. O'Ferrall.

The treatment of pendulous tumours resolves itself into a description of the modes of operation required in particular cases.

In its simplest form the pendulous tumour seems to require merely the division of its pedicle by a knife-edged scissors or scalpel; but the point at which this division is to be effected requires consideration. If the section be made too near the bulb, an unsightly projection will remain after the operation; if it be done too near the other extremity of the pedicle, the integument, on retracting, will have a wound, and consequently a scar, much larger than would have been anticipated. Allowance then must be made for the elongation of the pedicle, by the weight of the bulb, and for the contraction of the stalk, which always follows its division,—the same process which renders it unnecessary to tie the neck of an uterine polypus close to the mucous surface, from which it has grown. The best mode of proceeding is to poise the tumour on the hand, and allow the surrounding skin to retract and recover its pristine position, and then to make the section of the pedicle a little below its origin. Should the nutrient artery be large enough to deserve attention, the jet of blood may be prevented by previously including the neck of the tumour in a provisional ligature, and when the section is accomplished, tying the divided artery. The provisional ligature may then be removed altogether. A slight touch of the nitrate of silver, just sufficient to produce a delicate white coating, will not only shorten the duration of the subsequent smarting, but lessen the probability of any re-action, especially of an unhealthy kind. Simple water-dressing will then complete the local treatment.

In operating on the adipose pendulous tumour, the extent of interference with the pedicle will be regulated by the presence or absence of fatty matter in its substance. If the growth extend through the neck into the subcutaneous cellular membrane beyond it, such an incision must be made as will allow of its complete extraction. In such a case the small cavity then left should be filled with lint dipped in olive oil, and the integument brought gently over it, to prevent an unnecessarily large cicatrix. The lint is then withdrawn, when suppuration is established, and the integuments brought together by adhesive plaster.

The proceeding in pendulous nævus is somewhat different, and must be adapted to the peculiar circumstances of the case. It is not usual for the pedicle, in such instances, to be entirely free from all traces of erectile tissue. Should the pedicle be implicated, or should the vessels of the cellular or dermoid tissues beyond it be hypertrophied, a simple section would be inadequate to the cure; hæmorrhage of a troublesome nature would be the immediate result, and reproduction of the disease the more remote consequence of such an imperfect procedure. The diseased part must be included in an elliptical incision, and thus freely and completely removed. It may happen that the erectile inflammation may extend irregularly, for a considerable distance, beyond the origin of the pedicle. In such cases the amputation of the pedicle alone would entail the consequences already alluded to, while the excision of the whole of the morbid structure might be forbidden by its extent, or by the importance of the parts in which it is found. The following is the mode I would recommend under such circumstances, and when the removal of the pendulous tumour is desired on account of the inconvenience it occasions:—The tumour being held horizontally, and on the stretch, the point of the style or nail cautery, described by Dr. Wilmot, should be passed through the cervix in several places, so as to ensure the obliteration of the vessels contained in that place. The whole cervix may be traversed by these punctures at one or several successive operations, according to its breadth. When the vascular character of the cervix is thus changed, its section may be performed, without risk of hæmorrhage. A series of seton threads would accomplish this object, but in a manner much more painful and tedious to the patient. The mode of obliteration of erectile tissues employed by Dr. Wilmot is, I know, a great improvement on the previous practice in such cases. Its adaptation to pendulous tumours, previous to their section, will, I trust, be found available, and I would venture to recommend it.

When a pendulous tumour is known, or suspected to be malignant, great care must be taken to remove the entire of the morbid parts. If the heterologous structure be confined to the bulb of the tumour, and the pedicle or surrounding skin be healthy, there can be no reason for doing more than simple section of the form; but the section should not, for obvious

reasons, be made too near the bulb. But should the neck of the tumour be thickened, hardened, or irregular, a free elliptical incision should be made in the integument beyond it, and all suspicious parts satisfactorily removed.—*Dublin Journal of Medical Science.*

ON FOREIGN BODIES IN THE AIR-PASSAGES.

Dr. Mason Warren terminates a paper on this subject as follows :—

1. It is unsafe to trust to the spontaneous expulsion of any substance, which is liable to increase in size from heat and moisture. This is more particularly true as regards children.

2. Metallic substances when engaged in the larynx or lodged in the lungs, may be trusted with more impunity. If flat they present an edge to the tube, so as to permit the passage of air on each side. When lodged in a bronchus, such a body becomes after a time, enveloped in mucus, so as to obstruct the free act of respiration; it is then forced upwards and the mucus is dislodged; the body again falls back, and remains quiescent until again covered with mucus, when the process of dislodgement is repeated.

3. If the substance is fixed in the bronchus and the patient young, the prospect of seizing it by instruments introduced into the wound (after tracheotomy,) is extremely small. In fact, the case in which Mr. Liston removed a bone with the forceps, is the only one perhaps on record.

4. Some doubts will arise, as to the propriety of leaving, in any case, a foreign substance for a period of time in the lungs, without an effort to remove it. Although it may finally become detached and ejected, fatal pneumonia is not uncommonly the result.—*Boston Medical and Surgical Journal*, Jan. 1, 1848.

THE USE OF THE CUPPING GLASS IN RETENTION OF URINE.

M. Vandenbroeck asserts that he has for twenty years replaced the use of the catheter in both sexes, by the application of a cupping-glass to the inside of the thigh. In nine cases out of every twelve, he states that emission of urine follows in a few seconds. This is not the case of course in mechanical retention.—*Dublin Medical Press.*

OBSTETRIC MEDICINE.

SPONTANEOUS EVOLUTION.

Mr. Edwards relates the following in the *Lancet* January 8th :—At 10 a.m., April 26th, 1847, he was summoned to a woman in her third labour. On examination the os uteri was found to be fully dilated, and the arm of the child protruded from the vagina. He proceeded at once to turn, but the feet could not be brought down in consequence of the vehemence of the uterine contractions. Under these circumstances, as symptoms of exhaustion declared themselves, it was resolved to use the perforator, but before the instruments could be prepared, the woman passed a large quantity of fæces, and immediately the arm disappeared and the breech presented. Two or three pains soon expelled the child, which had evidently been dead for some hours.

[These cases are not so rare as has been imagined, and according to Professor Simpson, would be still more frequent if timely assistance were not rendered. The proper practice is beyond a doubt to turn in the great majority of cases, where practicable; failing that, in many instances it would be necessary to resort to decapitation or evisceration. It should, however, be known, that Professor Simpson considers that where the process of spontaneous evolution is found to have considerably advanced, it is a sign that the pelvis is sufficiently large to allow of the completion of the process.]

FRACTURE OF THE STERNUM FROM MUSCULAR ACTION DURING PARTURITON.

The following case partakes of the interest which attaches to instances of fracture from simple muscular action, but it also has a peculiar interest inasmuch as there had been no evidence of disease of the osseous system as commonly happens in similar cases.

The narrator, M. Diez, attended a female, aged 32, in her fifth labour. The child was born before his arrival, but his attention was directed to a pain at the centre of the sternum complained of by the patient. She stated that, during one of her pains she had distinctly heard a cracking noise in this spot, and that the seat of fracture was perceptible to the hand. On examination a division in the bone was readily detected. The fracture was reduced with the greatest facility, and was kept in its place by a bandage and graduated compresses. Union was complete on the thirteenth day.—*La Faculdad.*

CHLOROFORM IN PUERPERAL CONVULSIONS.

Mr. Fearn, of Derby, exhibited chloroform in the case of a young girl, aged seventeen, in labour of her first child. The convulsions, which were severe, were first treated by bleeding and turpentine enemata. When seen by Mr. Fearn, they had recurred with great intensity, and the agitation of the patient was so great, that delivery could not be attempted. The exhibition of chloroform speedily induced a cessation of the convulsions, and she was then delivered by the crotchet. —*Medical Gazette*, February 11.

[It is a question how far the same result might have been attained, had the treatment not been premised by bleeding. Puerperal convulsions in general are marked by such strong signs of cerebral congestion, amounting in some instances even to apoplexy, that it is questionable how far chloroform, the effect of which is to induce cerebral congestion, could be rationally employed. In anæmic puerperal convulsions this objection would not apply.]

THE NEW CHARTER OF THE ROYAL COLLEGE OF PHYSICIANS.

[We have great pleasure in availing ourselves of the permission of Dr. Hawkins to publish the following letter in the *Provincial Medical and Surgical Journal.*]

18, Bolton Street, Piccadilly, London.
March 24, 1848.

Dear Sir,

As the terms on which the College of Physicians has offered to receive, under a new Charter, the physicians of this country, have been incorrectly stated, and imperfectly

understood, particularly as regards the date previous to which those proposed to be received should have taken their degrees, it is very desirable that this mistake should be corrected as speedily as possible, and that the manner in which the mistake has arisen should also be explained.

In the Clause of the proposed Charter relating to this subject, which has been lately circulated, the date assigned, as a limit for graduation, is January 1st, 1842; but this date was introduced under the supposition that the Charter would be granted in 1843 or 1844, and it would, of course, be altered (if any limit as to date be retained in the Clause,) in proportion to the time which has since elapsed.

The Clause, as circulated, is taken from a copy of the proposed Charter which was given last summer to the Committee of the House of Commons, and which was printed, with the evidence taken before that Committee. Now, this was a copy of the Charter in the state (professedly unfinished, beyond which it has never, in fact, advanced,) in which it was left at the termination of the discussions which the College had upon the subject with Sir James Graham. This copy is not only imperfect, but must be altogether deceptive, unless it be read in conjunction with a memorial, addressed to Sir George Grey, and printed also with the evidence taken before the Committee of the House of Commons, in which memorial the College expressed its desire to alter, in many respects, the Charter which had been before agreed upon.

Originally, in 1842, the College offered, as the commencement of a better system of classifying and registering the order of physicians, and all orders of the profession, to receive, without examination, all *bonâ fide* British physicians of the age of 26 years; but this offer called forth many remonstrances, as if it would be productive of some degree of hardship and injustice to those who had undergone examinations, and paid the full fees for their licenses; thence it happened that the restrictions were introduced which appear in Clause 5 of the proposed Charter, as to the manner in which degrees must have been obtained, and as to the age of the physicians to be received without examination; and the College being informed that, with the view of being thus received, many were hastening to obtain degrees whose education had hardly been equal to that prescribed by the College, for this reason the restriction was added as to graduation previous to a certain date. For similar reasons the restrictions were introduced which appear in Clause 4, relating to the Extra-Licentiates.

The views of the College as to the terms on which, under a new Charter, it could, with justice and propriety, receive British graduates without examination, have, naturally and properly, varied at different times, according as there has or has not been a prospect of a general legislative measure for the regulation of the profession; also, according to the variations which took place, from time to time, in the terms and enactments of the different general measures which were successively proposed. In the later bill proposed by Sir James Graham, there was a provision for a Supplemental Register, in which it was supposed that physicians might find a place, if there were any who had not been received by, and enrolled in, the College. But if, according to the principles which have recently been proposed for a General Medical Bill, it should be rendered absolutely necessary for registration, that all practitioners should be enrolled in the College belonging to their department in the country in which they practise; in this case it would certainly be right and necessary that physicians should be received, at first, into the College, upon broader and easier terms than might be just and proper, if no such general enactment should be passed by the Legislature.

Thus there are several important points in the new Charter for the College of Physicians, which, as they must be in some degree dependent upon the circumstances under which the Charter is to be obtained, have not been, and could not be, definitely settled; and the College would, I am persuaded, be truly glad to learn what are the opinions upon these points entertained by physicians throughout the country. Accordingly, I rejoice to see, that in furtherance of this wish, which was expressed by a Committee of the College to a Deputation from the Council of the Provincial Medical and Surgical Association, the Editor of the *Provincial Medical and Surgical Journal* has been good enough to invite physicians to communicate to the Council their opinions. And as it is clearly necessary that the points on which they are asked to form and express their opinions should be correctly stated, therefore I am induced to trouble you with this letter respecting some of those points which appear to be the most important.

I am, Dear Sir,

Yours faithfully,

FRANCIS HAWKINS.

To R. J. N. Streeten, Esq., M.D.,
&c. &c. &c.

MANCHESTER MEDICO-ETHICAL ASSOCIATION.

LIFE ASSURANCE CERTIFICATES.

[The following circular has been addressed by the Manchester Medico-Ethical Association, to the Directors of the several Life Assurance Offices.]

The members of the medical profession feel greatly dissatisfied that when referred to for certificates of health by applicants for Life Assurance, they should have difficulty in obtaining remuneration for their services. For evidence of the extent to which the feeling of dissatisfaction exists, the Committee of the Manchester Medico-Ethical Association would refer to the numerous complaints that appear in the medical periodicals, and also to the experience of Boards of Directors on this point.

The Committee in attempting to effect a settlement of the question would remark, that while on the one hand the claim of the Medical Referee is just and reasonable, so on the other a recognition of this claim would greatly subserve the interests of the Assurance Companies.

The duty which the Medical Referee is called upon to discharge is one involving great responsibility, since his report on the applicant's past and present state of health in some cases determines the decision of the

Directors in regard to the application, and in others may at a future time be made the ground for resisting the payment of the policy. It is moreover one of much delicacy, as he is thus often compelled, in telling the whole truth, to record particulars entrusted to him in professional confidence. It is further one, the due fulfilment of which, in many instances, militates against his own interests; for cases might be cited, where medical men in this way have become involved in trouble through attacks on their honour aud integrity, as well as on their professional skill. Finally, though all communications to the Office are termed "strictly confidential," breaches of good faith are not altogether unknown; and even where secresy is maintained it will sometimes happen that, in the event of a policy being refused, the displeasure of the applicant and his family, falls upon the Medical Referee, from a suspicion that he has given an unfavourable report. From these considerations it must be manifest that the profession have a just claim, on one party or the other, to remuneration for the certificates required for Life-Assurance.

This being assumed, the Committee would now proceed to another question, viz., which of the parties ought to pay the fee—the Assurer or the Company? Here the Committee would observe:—

1st. That the condition of a certificate of health being given by a Medical Referee is one imposed by the Company, solely, with the view of aiding them to decide whether they can accept the proposal of the applicant with safety to their own interests.

2nd. That the entire benefit to be derived from the certificate is received by the Company; that it is alone valuable to, and can only be used by, the Company. If the certificate report favourably, it is an additional security to the Company; if unfavourably, it protects the Office from a bad life; and if unfaithfully, it may at a future period be used as a ground for vitiating the policy.

3rd. That if the certificate disclose, in even a small proportion of cases, a single fact concerning the health of the Assurer, which might be overlooked by the Medical Examiner for the Office, or which from its obscurity could not be detected by one a stranger to the applicant, and this will scarcely be denied, then its value to the Company, were there no other reason to adduce, would be clearly established.

4th. That either the certificate or instructions founded upon it, are commonly forwarded to the Medical Examiner of the Company, and consequently will thus in general prove of importance in directing his examination.

5th. That when disputed claims have been taken into courts of law, the certificate of the Medical Referee has usually been set forth as the basis of the contract, and as the evidence on which the policy was granted.

6th. That some Assurance Companies have no medical examiner of their own, but trust to the report made by the Medical Referee of the applicant.

Lastly, that several Companies recognizing the just claims of the profession, "pay every Medical Referee to whom they apply a fee for his services."

From all these considerations the Committee are led to the conclusion that the Company alone is responsible to the profession for an adequate fee.

The Committee beg to assure the Directors of their earnest conviction that the adoption of some arrangement by which the profession might be called upon to discharge this duty with impartiality, and at the same time receive a fair remuneration for the service, would prove of signal advantage to the Companies.

As the practice now is, the Referee has, in general, no communication with the applicant before making his report. The schedule is sent to him direct from the Office, and contains no suggestion as to the propriety of a consultation, but simply enquires—"When did the Referee see the applicant last?" and "What was the state of his health at that time?" Hence, has arisen the complaint, sometimes made, that the schedules are carelessly filled up, and that they supply little information of value to the Office. The Committee submit that this loose mode of reporting on the health of an applicant is at once hazardous to the character of the Referee, and injurious to the interests of the Company. They would also refer to the advantage which a more careful examination by the Referee, would secure for those Companies that insure diseased or unsound lives.

The Committee have carefully weighed the arguments commonly adduced in support of the course at present adopted by most of the Companies, and concede to the Directors that objections may be raised to an arrangement whereby the payment of all medical fees shall fall on the Office alone. The only arguments, however, which the Committee need refer to, are these:—That some risk would be incurred of fictitious applications being made at the instance of unprincipled medical men for the sake of obtaining the fees. That in cases where the proposal for assurance is declined, no profit accrues to the Company. And that the medical expenses preliminary to the contract between the Office and the Assurer ought, in fairness, to be divided equally between the two parties.

With a view to meet these objections, and at the same time to maintain the conclusion at which the Committee have already arrived, they beg to submit to the Directors the following Proposals—assuring them of their anxious desire that a removal of the difference which has engendered so much dissatisfaction in the profession, may now at length be effected through the instrumentality of the Manchester Medico-Ethical Association.

PROPOSALS.

1st.—That the Assurance Companies pay a fee to the Medical Referee of the Applicant for Life-Assurance, on the understanding that the former, before making his report, have, when circumstances permit, an interview with the said applicant.

2nd.—That the agent of the Company require of the Applicant for Assurance, at the time when the proposal is made, the payment of his proper share of the medical expenses.

3rd.—That the fee paid by the Office to the Medical Referee of the Applicant be—

For a Policy under £500, half-a-guinea.
For a Policy of £500 and upwards, one guinea.

GLOUCESTERSHIRE MEDICAL AND SURGICAL ASSOCIATION: THE INCOME TAX.

To the Honourable the Commons of Great Britain and Ireland, in Parliament Assembled.

The humble Petition of the Council of the Gloucestershire Medical and Surgical Association, acting in behalf of that body,—Sheweth,—

"That the members of the Medical Profession are at all times, and in many ways, called upon to give their time and services to the public without remuneration.

"That most of the Hospitals and Dispensaries in the United Kingdom are served by Medical Men without any compensation whatever for their time and labour.

"That a large number of the Medical body, are compelled by the existing condition of the Profession to accept appointments under the new Poor Law, not only without adequate recompense, but very often at positive pecuniary loss; while their duties expose them to serious risk of their lives from fever and other infectious disorders.

"That while the members of the Medical Profession are required to expend a large amount both of time and money in the acquisition of professional knowledge, the emoluments of medical practice are notoriously enjoyed to a great extent by persons who have passed through no such preparatory studies, and are in no way qualified to undertake the treatment of disease.

"That the gains of the Medical Profession are generally so small, that an argument has been raised upon this fact against enforcing universally a standard of medical education sufficiently high for the welfare of the public at large.

"That, as a consequence of this state of things, the various corporate bodies which have been entrusted with the power of granting Licences and Diplomas, are encouraged and enabled to undersell each other in their requirements of candidates; and thus to create a supply of Medical Practitioners greater than the needs of society demand,—thereby diminishing, by excessive competition, the profits of the Profession, and at the same time endangering the lives of the community for their own selfish and mercenary ends.

"That the national revenue is already enriched at the expense of the Medical Profession by the receipt of imposts upon patent medicines and indecent advertisements,—to the great injury of the public health, and the no less scandal of public morals.

"That the truth of the above assertions has been established by abundant evidence before Committees of your Honourable House.

"Your Petitioners therefore humbly pray that, in consideration of these statements, your Honourable House will be pleased to allow the professional incomes of qualified Medical Practitioners to be exempted from additional Taxation; at least, until such time as the Legislature shall see fit, by some comprehensive enactment, to remedy the present anomalous condition of the Profession, and secure to its members a reasonable share of those emoluments which are derived from the public for services which they alone are competent to render.

"And your petitioners, as in duty bound, will ever pray for the welfare of your Honourable House."

[The foregoing petition was presented, as the last clause will shew, on the lately proposed increase of the Income Tax being brought forward in the House of Commons. It is, however, sufficientiy obvious that it is equally applicable to the continuance of the Tax on Income in its present form, and although, as we feel convinced, the members of the Medical Profession in this kingdom would be the last to wish to embarrass in any way the affairs of the Government, we trust that when the fitting time comes to re-consider this question, the impost will be so regulated as to bear more equally and equitably, and relieve the Medical Practitioner from a comparatively excessive charge upon the hard-earned labours of an anxious, and too often dangerous calling.]

PRINCIPLES OF MEDICAL LEGISLATION.

The subjoined form of a Memorial, in favour of the Principles of Medical Legislation recently put forth, has been adopted by Medical Practitioners resident in the neighbourhood of Reigate:—

To the Right Honourable Sir George Grey, Baronet, Her Majesty's Principal Secretary of State for the Home Department.

Sheweth,—

That your memorialists being legally qualified members of the medical profession, have read with great attention and approbation a paper, entilted "Principles of a General Measure for Medical Reform," which have been unanimously agreed upon, as the result of several conferences, held by a Committee, representing the different sections of the medical profession, and which your memorialists are informed have been submitted to the head of the Home Department.

The undersigned, after due consideration, are of opinion that a legislative measure founded on those principles, will be eminently conducive to the public welfare, and will be generally satisfactory to the profession itself.

The undersigned therefore pray that Her Majesty's Government will adopt these principles, and promote the completion of them, in due form, as an act of the legislature.

PRIVATE BAPTISM OF INFANTS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Will you permit the insertion in your columns of a few lines suggested by your correspondent, Mr. Cooper's, complaint against the clergy of his neighbourhood for requiring a medical certificate of danger in all applications for their ministration of private baptism.

He says, "Hitherto I have declined giving the necessary document, as I can only regard such a demand on the part of the clergy, as tending to fasten unduly a solemn responsibility on the medical profession, which naturally belongs to themselves."

There is reason "in roasting of eggs," and I think there would be some reason in this roasting of his clerical neighbours, if Mr. Cooper had shewn that they have all graduated in medicine, but as I presume this is not the case with any of them, and that a Bachelor Curate, fresh from the University, ignorant of the mysteries of teething, and innocent of convulsions, may be the last person capable of forming a right judgment of dangerous symptoms in infantile ailments, I hope I may, without offence, suggest that Mr. Cooper endangers the character for courtesy, which is one of the attributes of our pro-

fession, by refusing to bear a brother's burden, for the sustaining of which neither his education nor his natural ability has fitted him. I do not apprehend that the clergy generally, in the diocese of Norwich, make a medical certificate a *sine qua non* of compliance with a request for a private baptism. If any act so rigidly, I can only conclude that they have been driven to do so, in order to check the imposition of parents, who raise on all occasions an alarm of "the child in danger," to save themselves the trouble of carrying it to the church.

The solemn responsibility in the matter resting upon the clergy consists in not baptizing children privately, without great cause and necessity, and in not deferring to do so when they have been duly, and without any manner of collusion, informed that they are in danger of death. Now, I maintain that cases frequently occur, in which a clergyman can only conscientiously acquit himself of his responsibility, in this particular, by dividing it with the medical attendant; and I have not that opinion of the members of our profession which would permit me to suppose that they do not aid, as a body, cheerfully their neighbours of the kindred profession, who, distrustful of their own opinion in a matter which lies beyond their province, would rely upon the judgment of those who are qualified to form one.

All quackery is to be discouraged, and no one should be blamed who pays a wholesome deference to the proverb, "*Ne sutor ultra crepidam.*"

Both the clerical and medical callings are beset with anxieties and cares. In innumerable instances the parson may and does give invaluable and ungrudging assistance to us doctors, and I am sure I am doing but justice to ourselves when I say, it is as much a pleasure as a duty with us to act upon the principle of "give and take" in our intercourse with the clergy.

I am, Sir,
Your obedient servant,
G. S. SNOWDEN.

Ramsgate, March 24, 1848.

MEMORIAL TO DR. BERNCASTLE, SURGEON TO THE CROYDON UNION.

We, the undersigned Medical Officers to the Cheltenham Union, beg to offer to you our sincere and heartfelt condolence on the late ill treatment you have received from the Board of Guardians of the Croydon Union, who, after refusing the unfortunate woman, Hopkins, parochial relief, (and, as we consider most unjustly,) with the intention of disguising their own censurable conduct, endeavour to pass it over by throwing the onus of the blame upon you.

On a careful review of the entire circumstances of the case, and duly considering the positive orders of the Relieving Officer, that you were not to consider Hopkins as a patient of the Union, we cannot but agree that you were entirely free from censure, and in fact treated her with the greatest kindness and humanity.

W. P. Brooks, M.D., Surgeon to District No. 2.
William Gregory, Surgeon to District No. 3
William Dalton, Surgeon to District No. 4.
Frederick Hyett, Surgeon to District No. 1.

Medical Intelligence.

APPOINTMENTS.

W. P. Brookes, M.D., has been appointed Visitor for the Cheltenham District of Lunatic Asylums, in the room of Dr. Boisragon, resigned.

M. Laugier has been elected Professor of Clinical Surgery at the Faculty of Paris, in the room of M. A. Berard, deceased.

M. Huguier has been elected a member of the Academie de Médecine. MM. Lallemand, Larrey, Ricord, Guersant, and Chassaignac, being the unsuccessful candidates.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members, Friday, March 17th, 1848:—F. Wilkinson; G. B. Masfen; J. Shorts; H. Haden; S. M. Shircore; J. S. Helmcken; R. Laycock; H. G. Martelli; F. A. Willington; M. Coleman; J. Bailey; W. T. Alexander.

OBITUARY.

Died, March 4th, at Clifden, county of Galway, of fever, C. Bodkin, Esq., M.R.C.S.

March 4th, at Upper Merrion Street, Dublin, Percival Hunt, M.D., Fellow and Vice-President of the College of Physicians, Dublin.

March 9th, at Upper Merrion Street, Dublin, Percival Banks, M.D.

March 11th, at Tunbridge Wells, aged 80, —— Nelson, M.D., formerly of Wimpole Street.

March 16, in Great Stanhope Street, aged 65, Sir Richard Hunter, M.D.

March 18th, at Dublin, aged 82, Alexander Jackson, M.D., Physician to the Richmond Lunatic Asylum.

March 22nd, aged 40, of fever, Richard Cranfield, M.D., Medical Attendant of the Fever Hospital, Dispensary, and Workhouse, Enniscorthy.

Recently, at Tulla, county of Clare, of fever, James Frazer, M.D., Physician to the Tulla Dispensary.

BOOK RECEIVED.

The Value of Embryonic and Fœtal Life, legally, socially, and obstetrically considered. By Thomas Radford, M.D., F.R.C.P.E., Consulting Physician to the Manchester and Salford Lying-in Hospital. 8vo. pp. 25.

TO CORRESPONDENTS.

Communications have been received from a Graduate of the University of Aberdeen; the Birmingham Pathological Society; Mr. F. Bainbridge; Dr. Simpson; Mr. G. S. Snowden; Mr. Crompton; a Licentiate; Mr. Worthington; Mr. W. W. Cooper; Dr. Oke; Dr. Berncastle; Dr. Seddon; Mr. R. Allen; Mr. J. J. Millard.

It is requested that all letters and communications be sent to Dr. Streeten, Foregate Street, Worcester. Parcels and books for review may be addressed to the Editor of the Provincial Medical and Surgical Journal, care of Mr. Churchill, Princes Street, Soho.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

REMARKS ON THE PRESENT ASPECT OF MEDICINE.

By W. Newnham, Esq., Farnham.

Whether it be true or false—just or unjust—a fact or a calumny, shall not be discussed on the present occasion; but justly or unjustly, it has been remarked of the medical profession, that it is particularly prone to jump to a conclusion without sufficient reasoning,—to adopt this conclusion most heroically,—to retain it most pertinaciously,—and to be driven from it ultimately, not by the process of conviction, but by the quiet ousting of one favorite hypothesis, through the fresher charms, and newer attractions of some younger competitor.

The history of the healing art would give countenance to such an assertion; and within the memory of some of my readers, who, like myself, have been conversant with medicine more than forty years, it would not be difficult to chronicle the rise and fall of many an ingenious system; or the enthusiastic admiration of some potent medicine, which has enjoyed its little hour of idolatry, and has then been thrown aside as useless. We, too, may have witnessed the prurient fondness for novelty on the one hand, and the condemnation of that which is new on the other, simply because it is new. Perhaps we have been partakers in the enthusiasm of the one or sceptism of the other: and perhaps by the mere influence of age, we have arrived at juster, soberer, and more lasting views, simply because sexagenarian feelings have become less acutely sensitive, and the voice of reason is more distinctly audible, in proportion as that of passion has become feebler.

But it was reserved for the present day to witness the resurrection of an exploded system of medicine, which has been resuscitated under high sanction, and which is prophetically destined to run a prosperous day of admiration, simply because it is so very convenient to all those who wish to save themselves the trouble of thought, and the burden and responsibility of the treatment of disease. The authority of its foster parent will protect its feeble life; and its native attractions will ensure a host of admirers, among those who prefer throwing the responsibility of consequences upon an unseen unknown agent called nature, rather than incur the onus of directing these efforts towards their right end,—of controlling them where they are excessive,—supporting them when languid,—or supplying them when defective.

These observations have been called up by the "Natural History of Disease,"—a new name, under the disguise of which it is impossible not to perceive, that with some slight modifications, this new doctrine is a resurrection of the old "expectant system of medicine," with all its exploded and entombed errors,—*exploded* from their awful consequences, and *entombed* by the wisdom of our progenitors.

It would be inconsistent with the plan of my present communication, to attempt a history of the expectant system of medicine, or to do more than briefly to point out a few of the fallacies on which it rests its claim to respect and admiration.

Its first principle is erroneous, because the event is never left to a natural terminaton. It is true, that medicine is proscribed, but other means are employed—such as diet, regimen, repose, air, temperature, water externally and internally, attention to mental conditions, &c., &c. Now, it is obvious that these are employed, for the purpose of controlling, or aiding, or modifying nature's processes; and if so, they are employed *quasi* medicinal; and it follows, that if it be permitted to employ one *modifying agent* in the treatment of disease, it must be also permitted to retain another modifying agent,—and *à fortiori*, it must be *necessary* to employ any medicinal agent which can effect the same purpose in a quicker, safer, easier, and more perfect manner; and this is the legitimate dominion of medicine. Failing, therefore, in its first principle, the basis is unsound, and the superstructure crumbles into atoms.

Not that we would be supposed to favour that heroic system of treatment which has been gradually expiring for many years, and from whose ashes has arisen this renovated expectant Phœnix. We have seen the grievous errors committed by the injudicious *heroism* of some of our body, and we trust have learned wisdom by their, and our own mistakes; but the antithesis to wrong is not necessarily right, and I venture to believe that the passive indolence of leaving disease to the tender mercies of nature, will destroy many more than the ruthless havoc occasioned by the *by-gone* "nimia diligentia medici." I believe I may safely appeal to all diligent, and learned, and unprejudiced practitioners in medicine,—not to those who have spent their days in indolent scepticism;—not to those who have been forced into the profession by the pressure of circumstances;—

not to those who have pursued it as a means of subsistence only;—not to those who have been disappointed in life;—nor to those who have pursued the well-beaten path of routinism, but to those, who, sincerely attached to their profession, and deeply imbued with its learning, and *successfully* engaged in its practice, and supported by the esteem of their friends, and devoted enthusiasts to the good of their patients, whether they have not justly calculated upon a certain effect from certain remedies within a given time; and whether they have not always witnessed that effect, more or less happily developed, except in those cases in which subsequent events have shewn that they were in error? If, indeed, such has not been the case, the prescriber has either been wrong in his diagnosis of the malady, or very unhappy in his choice of remedies, or very unfortunate in his selection of patients.

It might, perhaps, be enough to leave this subject where it is, but feeling as I do, the importance of at least attempting to stem the torrent of so fascinating and so overwhelming a tide of prejudice, I shall venture to detain my readers, not as the advocate of hyper-activity in medicine, but as the determined enemy of that indolence which would suffer the patient to die without one strenuous effort to save him.

One fundamental error of this system is that of leaving it to *nature* to remedy that which is *unnatural*. We shall admit the *vis medicatrix naturæ*; we shall admit that nature ever tries to restore all manner of lesions in her economy; and we shall admit, that it is folly and madness to contravene her efforts. But then, we must also admit, that in every instance disorder is (as the very term implies,) a deviation from nature's established functions, and a disturbance of all her regular agencies. We must also admit, that the *vis medicatrix* is imperfect, often failing in its effects, at other times producing results which are in themselves disease, and at others yielding to the agency of the destroying cause; we must admit that her curative efforts are frequently attended with violent re-action, which requires to be moderated; and we must admit, finally, that the *natural history* of disease *uncontrolled* is too frequently the extinction of life.

We have said that it would be folly and madness to contravene nature's curative efforts. Undoubtedly it would. Suppose a simple incised wound to be repaired by nature by the formative or agglutinative process, it would be folly and madness to *contravene this process* by keeping the edges of the wound asunder; but it would at least be equal folly and madness not to aid nature in the accomplishment of her process by bringing the edges of the wound together, removing extraneous bodies from its surfaces, and maintaining them in undisturbed apposition.

So again with the specific disorders—measles for instance; this must run a definite course, and if it be a mild case, it does as well under the marigold tea of the old woman, the handmaid of nature, as it does under the influence of more powerful articles of the Materia Medica. Here the practitioner may stand by and observe, and leave nature to her own agencies. But during the course of measles, the lungs, the brain, the mucous surfaces of the alimentary canal, are very apt to suffer; and is he then to look on, and allow disease to run its destroying course, and to say to a patient suffering from consecutive pneumonia, "wait," and to expect that by this talismanic word the disorganizing agencies will be controlled? Surely there is deep criminality involved in such a proceeding, and yet such would be the result of pursuing the principles of expectation in medicine. We must never forget, however, that this revival of a long exorcised ghost, has been evoked by the cruelties of that heroic system, which under these circumstances would have bled repeatedly *ad deliquium, coup sur coup*, and then would have rapidly placed the patient under the influence of mercury, and the sufferer would have apparently recovered, most slowly, only to fall a victim to phthisis. All this was very bad, but it was not worse than standing supinely by, and tauntingly advising the patient to "wait," aye, "to wait," while the folds of his shroud were drawn more closely around him, and until his last breath had been drawn in *expectation!*

But after all, the great field of battle for these respective treatments is FEVER! It is manifest that this system of *waiting* can attach only to *acute disease*, —to forms of malady which possess a definite though, perhaps, not a well understood course; and that while we admit the value of a wise expectation under some circumstances, we also insist that there are other circumstances in which this expectation would be criminal, and in which prompt and energetic measures are required to avert fatal consequences. The first step, therefore, which can be safely taken in this crusade against medicine, is to distinguish the cases which will do well, if left to themselves, from those which, if not treated energetically, will terminate fatally. But how is this object to be accomplished? Is it by pursuing the natural history of disease, and leaving the patient to die, without one serious effort to save him, till a sufficient number of facts have been accumulated to decide the question; or is it by greater and closer attention in distinguishing disorder,—in selecting medicinal agents,—in watching and honestly chronicling their effects, and in recording the successful and unsuccessful cases,—the cases in which the efficacy of medicine may be fairly traced, and those in which it seems to have been useless or injurious, distinguishing their peculiarities? Surely the latter is the only secure method of enlarging the boundaries of our science, and of snatching it from the quackery of the do-nothing system.

With regard to the treatment of fever, there are many of my readers who can remember when bark and port wine were considered as the panacea for this form of malady,—who can recollect the revulsion from this treatment to that of cold affusion,—who can trace the subsequent history of their professional life, in the recommendation of bleeding, and of mercury quietly administered, so as to induce gentle ptyalism;—there are those who can well remember the localization of fever to some one irritated organ of the economy, varying according to the occasionaal circumstances of

its production, or the peculiarities of the individual constitution, or of the prevailing epidemic, and its remote and collateral causes;—there are those who can well remember that this comparatively rational doctrine has been narrowed by some professional exclusives, who could see only arachnitis on the one hand, or gastro-enteritis on the other, as the sole cause of fever; and of later years we have been told that all these supposed causes are but consequences, and are themselves dependent upon changes in the blood, induced by fever, and so disturbing all the organs of the animal economy. And chemistry has shewn that these changes do occur, and thus we have again fallen back upon the humoral pathology. Now, although we are quite ready to admit the established fact of these changes in the blood *during* fever, yet we cannot admit as demonstrated, that these changes are the *cause* of fever, since they may be its consequences; nor that the several organs are disturbed from this cause, since they may have been disturbed beforehand, and it is clear that they are very unequally irritated; much less can we admit, that any one organ, or series of organs, is the cause of the evil. But with all these, and many more ill-defined and undetermined questions, is it wise,—is it prudent,—is it scientific,—is it just to ourselves or our patients, to stand quietly by, and watch the ravages of disease, till the case becomes hopeless, without trying to moderate the excessive actions,—to restore disordered secretions,—to watch over all the organs and functions of the system, and relieve the first symptom of embarrassment, and maintain, as far as possible, the harmony and integrity of the system. Even here then the doctrines of expectation are most cruel and unscientific, but much more so in chronic malady, where there can be no pretence of a definite course to run, and when, if left to itself, disease will usually exert a destructive influence over organs which are essential to life.

An illustration of this position occurs to me in the history of two parallel cases; both happened to children;—both were deep-seated abscess in the neck;—both threatened suffocation from the pressure on the trachea. One was left to nature, and the little victim of the expectant or natural-history system was early destroyed, while the other was relieved by a careful puncture, and life was saved, and health quickly restored. Surely the remorse of the former medical attendant must have been poignant, while the reflections of the latter must have been most enviable. It may be said that this was surgical treatment, and so it was, but it was adopted as a means to an end; and the question is not, *what kind* of interference with nature, but whether any rational treatment is to be adopted.

It is manifest that in order to secure any logical standing place for this system of expectation, it must be assumed that *all* disease has a regular course, and a favourable tendency; yet nothing can be more untrue, for it is only acute disorder, which in the present state of our knowledge can even be presumed to have such a course; and even here it must be allowed, that the uncontrolled tendency is not always favourable, but that on the contrary, in a great number of cases, the most dangerous symptoms arise, requiring the most active and the best directed efforts, to prevent their fatal termination; and again, we see the insecurity of the pretended "natural history" of disease, which is about equivalent to Whiter's quaint title, the "*Disorder of Death*," which *he* assumes to be *remediable* under the balmy influence of the grave.

Originating in the seventeenth century, bibliographical researches enable us to trace much learning and talent expended upon this heresy, and many valuable treatises for and against, which we have not now time to follow; I shall therefore only notice a satirical treatise, published in 1695, by our countryman, Gideon Harvey, and entitled, "Art of Curing Diseases by Expectation." This was translated, and published two years afterwards, at Amsterdam, with a more offensive title, viz., "Ars Curandi Mobos Expectatione; item de Vanitatibus, Dolis et Mendaciis Medicorum." How far the translator intended the latter part of his title to be a commentary upon the former, shall not now be estimated, but I must for one moment refer to the frontispiece of Harvey's original work, in which are engraved the apothecary, with his syringe and phials, the sick man anxiously sighing for the prescription from which he hopes for relief, and the physician replying to the officious zeal of the former, and the deep solicitude of the latter, by this simple term, (equally full of despondency to both,) "*Expecta*"—*Wait.* A pithy exclamation, calculated to excite a smile in reflecting upon the past, but in sober earnest, no joke to the patient, and full of the most ominous forebodings.

It is necessary in forming a judgment concerning the curative powers of nature, to throw aside equally the vacillating character of certain practitioners, whose physical conformation, or long acquired habits, lead them to be fearful of the effect of the most simple remedies; and the hasty, intemperate rashness of others, who prescribe the most energetic treatment upon trifling occasions. Both are exceedingly mischievous, the former by allowing the patient to die without an effort to save him, and the latter by destroying his patient through misplaced activity. It is neither by the one nor by the other, that the expectant or natural system can be tested, but only by the results of wise, and enlighted, and unprejudiced experience.

We cheerfully admit that the greater number of acute maladies pass of themselves through the successive periods of incubation, gradual development, highest degree of intensity, decline, and convalescence, without the employment of serious remedies. But then, we insist that in every one of these stages, nature often fails in her duty, or overacts her part, or allows some great secondary organic mischief to be produced; and that the only wise and safe plan is,—not indeed to *contravene*, but to *direct* her efforts,—to *watch*, but not to *wait* upon, her movements,—to check what is redundant, and arouse what is inactive,—and supply what is defective,—and not to postpone this conduct, till death has put his seal upon futurity.

We are quite aware that the fondness for expectation may be the result of a wish to proclaim ourselves free

from the prejudices of the vulgar in favour of physic, and as accompanying a mental statum inaccessible to them. But prejudice exists at both ends of the scale of intellect; and the prejudices of the learned are equally narrow,—equally intense,—equally difficult of removal—more bitter, and more injurious, because of their power to disseminate, and uphold, and extend their specious errors.

The most eloquent and the most learned advocate for the expectant system is, perhaps, Voullomme, whose essay gained the prize offered by the Academy of Dijon, in 1776. This celebrated author admits as the basis of malady, a certain morbific principle, which presents an obstacle to the free exercise of the functions of the animal economy; and a certain vital principle which is disturbed by this obstacle, and exerts and sustains various movements, for the purpose of restoring the lost order and harmony. And on this feeble basis he works out the distinction between active and expectant medicine. But he proceeds to show that in order that the latter or expectant medicine may be safe, the efforts of nature must not be *too great*, nor *too languishing*, and that they must not *endanger the safety* of any one organ.

Such is the scheme of this redoubted champion of expectant medicine, and I presume there are few who would think it desirable to interfere while nature was doing her own work, and so long as her efforts were neither too great nor too small, nor the integrity of any organ was endangered. Such is the feebleness of expectant medicine, or the natural history of disease, when honestly and fairly practised at the bedside by one who, during a considerable life, had thrown his whole energies into his profession, who had literally studied and experienced every day of that life, and had not been disappointed in his day-dreams of eminence. I will venture to add, that the testimony of all those who have so done, and learned, and watched, and reasoned for thirty years, will confirm the fact that their power of distinguishing and controlling disorder has greatly increased, and that, in the great majority of cases, when called on to prescribe, they are certain of the effects they may expect and will meet with from the remedies employed. Rather, therefore, than take up this expectant system of treatment as a substitute for the medicinal; rather than moot the question which is abstractedly best, active and energetic watchfulness, or indolent and careless contemplation, for the patient, let us seek to determine what forms of malady may, notwithstanding their apparent violence, be left to very simple agencies, because they have an essential tendency to a favourable termination, and will generally be cured by the simple resources of nature, *from those*, which if left to themselves, will terminate unfavourably,—a question which, after all, will greatly rest for its solution upon the constitution of the patient, rendering each case an individual study, and requiring the adaptation of means to its peculiarities. Here, then, we return to diligent active medicine, wisely directed and controlled, by zeal on the one hand, combined with knowledge, and by prudence and experience on the other. With such views it is quite possible that active treatment may be required in a case which has a natural tendency to recovery; *not* against the malady itself, but against certain symptoms, which if uncontrolled would prevent this natural tendency from being developed and sustained.

If, by attracting attention to the natural history of disease, the prescriber may be alienated from an *exclusive* attachment to drugs, and can be led to a profounder study of regimenal and hygienic treatment, *good must arise*; but unqualified, *unmitigated evil*, if by these attentions he is enticed away from the far more powerful resources of medicine,—resources, which if wisely directed, will produce equally good effects in a shorter time, and with less expense to the constitution. Even those forms of malady which are admitted to possess a natural tendency towards recovery, may not be abandoned to the sole resources of nature, for these, too, require active vigilance to second and support nature's agencies, and carry them on to a perfect restoration of health.

In cases, where the opposite tendency is remarkable, and these very largely preponderate,—where the functions generally are disturbed, the circulating system agitated, the distribution of animal heat irregular, the secretions perverted, spasms and other affections of the nervous system present, too great or too little activity, or perversion of the sensorial and intellectual functions, and various other forms of disturbance, what is there to be expected from the conservative influence of unassisted nature? Then, indeed, it would be folly, and madness, and wickedness, to stand by, idle spectators of our friend's destruction, and apply the last flattering unction to our souls, that at least he had died a natural death. Such a proceeding is not to be tolerated; and even in the only cases to which expectant medicine can be at all applicable,—those of acute disorder,—it is very seldom indeed that we can find such disorder simple and uncomplicated, and unless such should be the case, the basis upon which this hypothesis seems to rest is subverted; since for a safe-conduct of the malady to a happy termination, these complications will require the greatest care, and most delicate attention—a sort of alternation of action and expectation well calculated to test the strength of the medical man, whose greatest value consists in knowing *when* to be active, and *where* to avoid disturbing nature's agencies, and in not only *knowing but doing*.

If by *expectation* he really intended *observation* on the course of the malady, and supplying the appropriate remedies, which such watchfulness may indicate, only in such order and in such doses as shall most safely lead to the convalescence of the patient,—accomplishing this object, by the mildest known efficacious remedies, and attending diligently to all the beneficial influences which may be conveyed through the moral nature of man, as well as to all similar impressions conveyed by attention to diet, and regimen, and air, and quiet, and the general proper management of a sick room; why this is only to abstain from that which would be a positive hindrance to nature's agencies, and here we go hand in hand with our expectant physician. But this will not satisfy him, because this

would involve the employment of every remedy calculated to favour our object, and assist nature in the accomplishment of her views, and assuredly this would be to interfere with the natural history of disease.

It is not easy to bring this question to the test of experience, for in the first place men judge very differently as to the form and degree of malady; they arrive at very different opinions of the self-same disorders; and their inveterate prejudices lead them to find their preconceived notions confirmed. Then, a great majority of diseases would get well of themselves, and the touchstone of utility of treatment is the experience of an honest and true heart, with regard to those frightful forms of malady which threaten the extinction of life; and in man's present imperfect state, one despairs of obtaining such results.

It should ever be borne in mind, that the administration of medicine is *one* important means of controling disease, and of favoring returning health; let it, in fact, be called a portion of our hygienic agency; allow it a place in the scale of influence at least equal to other means of this description; and then, *if the one be necessary, so will be the other.* Then, let us not indolently sit by, and contemplate the ravages of disorder, but while we prudently and cautiously avoid all means, hygienic and regimenal, as well as medical, which may be calculated to contravene nature's efforts, let us also wisely and zealously employ all the means in our power, *medicinal as well* as *hygienic* and *regimenal*, to favour this result; let us anticipate if we can what have been supposed to be the critical terminations of malady, by acting upon the secretions; and if we cannot effect this anticipation, let us supply such lack of service by subsidiary influence; let us carefully avoid that blind and misplaced security in the curative powers of nature, which would lead us to overlook or undervalue important remedies, on the hollow pretext of not interfering with the natural history of malady; let us not cruelly delay the application of remedies until the golden period for action has escaped us, and the time in which we could be useful to our patients has fled for ever,—fled with the *first* lengthening, and then fast receding, shadows of life. Even in the happier forms of malady, let us carefully endeavour to screen our patient from those complications which may prevent an agreeable result; let us try to *second* the salutary efforts of nature, and control her too great vehemence of action; while in the severer, as well as in the slighter disorders, let all our remedies be employed *cito tute, jucunde.*

(To be continued.)

SHORT NOTES OF THE OPINIONS AND PRACTICE OF THE LATE JOHN PEARSON, ESQ., F.R.S., ON SYPHILITIC DISEASE.*

By W. S. Oke, M.D., Physician to the Royal South Hants Infirmary.

The Effect of the Venereal Virus upon Bones.—It is taken for granted in general that the bone is affected in the same manner as the periosteum, but no fair case can be shewn in which the bone was primarily affected by the venereal disease. If this effect were produced, it is necessary that the bone should become soft, so as to admit of dilatation, or that its bulk be increased by a deposit of new matter. The venereal virus attacks the cortical plates of the bones from the periosteum, and of those bones which are nearest the surface; the effects therefore just mentioned must have been seen if they did take place.

The bones certainly become soft in other diseases, as in scrofula, where the medullary part is attacked; but the only primary effect from the venereal disease which can be discovered, is death of the bone. There is not ulceration, as in scrofula, or a loose fragment, as in necrosis, but the solid part of the bone dies.

When the matter is under the periosteum, the bone always suffers, and as those bones are generally attacked which are nearest to the external air, a secondary effect is produced by exposure.

In the bones of the cranium the outer table is sometimes destroyed, but the disease does not often go beyond the diploë. [I remember to have seen a case of this kind in a young man, in which almost the whole of the outer table of the frontal bone was dead and loose, whilst the inner table did not appear to be involved. The dead bone was removed by Sir Benjamin Brodie.]

The membranes covering the base of the nostrils, formed by the maxillary apophyses, the vomer and the inferior spongy bones, being exposed to a stream of air, are very liable to become affected by the venereal virus. A carious state of one or more of these has always been connected with an ulcer in the nose. It may be doubted whether an ulcer can long exist on the upper part of the mouth, without being associated with some disease of the palate bone. Even in such a case, the disease generally begins in the membrane of the nose. Whenever, therefore, there is a viscid secretion obstructing the nostrils, or an offensive discharge, tinged with blood, with a sense of soreness about the part, a carious bone is to be suspected.

Again, when there is a small rising at the upper part of the mouth, a plate of bone will often be found bare; but when the greater part of the horizontal plate is carious, it is probable that the palate bone, vomer, and nasal lamella of the ethmoid bone, are in the same state. Sometimes along with this, the alveolar processes of the four front teeth are involved; but if the soft palate remain, the inconvenience is not considerable. The ossa nasi are never diseased, except when there has been great destruction of the soft parts.

Wherever examination can be made for local symptoms, it ought to be done, however much the patient may refer them to internal maladies, as many complaints may be discovered to arise from mere local causes, unconnected altogether with the venereal disease.

* Continued from page 149.

The venereal virus will occasionally attack the internal part of the skull, in a remarkable manner; the inner surface becomes scabrous, with a number of projecting edges or points. The patient has violent headache, pains in the muscles moving the head and neck, and symptoms of compression of the brain; the eyes and ears are greatly affected, and idiotcy is often the result. The brain being kept in constant irritation, becomes susceptible of the slightest excitement, which eventually brings on fits, resembling epilepsy, and the patient dies. From this deplorable condition recovery is never to be expected.

Treatment of Tertiary Symptoms.—The tertiary symptoms of syphilis cannot be cured with the same facility as the primary or secondary symptoms; from nine to twelve weeks will usually be necessary; or if the mercury has not acted fairly, the course will sometimes be required to extend even to fourteen weeks.

Treatment of Pustules.—Pustules in this stage of the disease should be made to dry as soon as possible, that the parts below may heal without exposure to the air; with this view it will not be expedient to use the warm bath, or any unctuous application.

If the crust remain moist and elevated, and there be an oozing of matter from under it, the most useful application will be a strong decoction of guaiacum shavings, with a little spirit; and when they separate from the skin, they are apt to leave deep foul ulcers, which are much disposed to throw out fungus.

Great attention is necessary to destroy the fungus, for, if neglected, the sore will either not heal, or leave an unseemly cicatrix, which will be very liable to give way. The best applications in this case will be a solution of the sulphate of copper, or of nitrate of silver, of such strength as not to give pain. The sores may be afterwards dressed with the Unguentum Hydrargyri Nitrico-Oxidi.

When mercury has been ineffectually employed, the cicatrix remains smooth, of a silky feel, and of a redder colour than is natural. On the contrary, when the disease has been completely cured, there will be a depression in the middle of the cicatrix, which will have as much roughness as the natural skin. As cicatrices are apt to give way, when even there is no return of the disease, they should be defended from the external air by some mild cerate.

Treatment of Enlargement of the Ligaments.—This symptom will require as full a course of mercury as the former, and will be benefitted by the vapour or hot bath. If the enlargement should not subside at nearly the end of the course, volatile liniments with camphor, or repeated blisters, may be applied to the part; and whether these last remedies are required or not, it will be necessary for the patient to wear a soap plaster, with mercury or without it, for some time.

Treatment of Nodes.—No particular mode of treatment is necessary, as recent nodes generally disappear during the course: should they be painful, immediate relief may be given by dividing the integuments down to the bone, and separating the periosteum for about a quarter of an inch. Exfoliation does not always follow. The wound should be dressed down with lint, to promote suppuration.

[This practice has an excellent effect in chronic or local thickenings of the pericranium from traumatic causes. I recollect one instance of this kind, of long-standing, and of very painful character, which was at once cured by my dividing the pericranium, and dressing it with dry lint till a small scale of bone was exfoliated.]

When the periosteum has been extensively affected with the disease, it has been found necessary to give the bi-chloride of mercury, in the dose of one-eighth of a grain, three times a day, for four or five weeks, before a course of inunction.

[The modern iodine treatment of these cases has an immense advantage over the mercurial, as will be seen in the following case. A few years ago a tradesman consulted me for a large node on the shaft of the left tibia, which had existed many months, and deprived him at length of all sleep. He had tried the usual treatment in vain, and even opiates had failed to exempt his nights from severe pain; indeed so great were his sufferings that he requested, as a last resource, that his leg might be removed. Five grains of the iodide of potassium were ordered for him three times a day, with five grains of the Pilula Hydrargyri every night. On the third night the pain subsided, and never returned. The nodes gradually diminished, and in six weeks he was quite well.]

If the tumefaction should not subside when the pain is removed, repeated blisters have been of use; but, notwithstanding this treatment, the bulk will sometimes last a good while; if, however, it is free from pain, and will bear pressure, no anxiety need be felt about it.

Treatment of Caries.—As there is generally a collection of matter about carious bone, it will be best to divide the integuments, in order to evacuate it, and bring away the loose pieces of bone, but in general the integuments ought not to be removed, unless they are much diseased. A small incision will suffice, and after the first inflammation has subsided, and good pus has been formed, the sore may be dressed down with lint, dipped into Bates' camphorated water, dry lint over that, and over all some mild cerate.

No particular effort need be made to keep the sore open, for if any small bits of bone should approach the surface, they can easily be removed by a small incision. Keeping the sore open for such an object, will only be painful and inconvenient.

Carious bones of the cranium are generally long in separating—sometimes three years. If both tables should be affected, it will be necessary to remove the

dead bone with a trephine; but both the cranial tables are so seldom involved, that such an operation is very rarely required.

No particular treatment is applicable, where the bones of the face are diseased. Bates' camphorated water or the Linimentum Æruginis may be employed; or if the internal bones of the nose be involved, lime water with a little of the above liniment may be used. The parts are to be kept clean, and as dry and easy as possible; and no strong efforts should be used to get away diseased bones, especially of the nose, till they are loose and vacillating.

After the bones of the nose are separated, there will probably be a considerable discharge of a yellowish matter for some weeks; and the same kind of matter will sometimes find its way through the puncta lachrymalis. This may arise from a diseased state of that part of the palate bone which ascends to form part of the orbit.

During the night the discharge will be very small in quantity, but will be much increased by the erect position and exposure to the air. As soon as the diseased bone is removed, the discharge will gradually decrease, and in four or five weeks entirely cease; there may be, however, other pieces to come away, and a year may elapse before they are wholly removed. When one piece has come away, the discharge is very great, and then ceases gradually; another piece brings on the discharge again, till it has exfoliated, when the discharge increases for a time, and then subsides as before.

If the bones of the palate should have been destroyed, a silver plate may be substituted; but if the soft parts are also gone, there will be no support behind, and the defect will be irremediable.

After the separation of the palate bones, it is best to introduce lint for some time, to obdurate the soft parts; for without this precaution the false palate will give great uneasiness. As the opening will in some measure become contracted, there will be greater probability of the false palate fitting at the end of six months than if introduced sooner.

Though the vomer should come away, the form of the nose will be decently supported so as to enable a person to mix in society; but if the softer septum should come away, the deformity will be considerable.

When the tibia is diseased, the bone being laid bare, the parts should be dressed with drying applications till exfoliation is completed; but should a considerable part be carious, perhaps half the bone, it ought to be taken away by means of a mallet and chisel, by which treatment the process of exfoliation will be shortened several months.

As the patient may suffer a relapse after the process of exfoliation, it is desirable the bone should be separated before the mercurial course is completed. This may be done when the bones of the face are diseased; but when the frontal or parietal bones are involved, it will be found more difficult—indeed, in such a case it is not easy to decide when mercury may be laid aside with safety.

A relapse may be suffered in two ways,—viz., by the contamination of the parts contiguous to those which are diseased; or by the recurrence of a spot of the secondary kind. In such cases as these, four courses of mercury may be required during a period of three or four years before the disease is fairly eradicated.

In support of this severe mercurial treatment, Mr. Pearson relates the following remarkable case:—

A woman underwent a course of mercury in the Lock Hospital for a syphilitic secondary eruption, and appeared to be cured. She went into the Asylum, and at the end of three or four months returned to the hospital with nodes, which were apparently cured by a second course of mercury. Sometime afterwards she had caries of the tibia and of one of the parietal bones, and was confined to her bed three months, whilst she underwent a third course of inunction. The portion of the tibia separated during the course, but that of the parietal bone did not come away till after three years. At the end of two months from the separation of the latter, her throat was found to be ulcerated and venereal blotches appeared on the skin. She then went through a fourth course of mercury for nine weeks, and has since remained well.

It is the practice of some,—of Hildanus, Louis, and Turner, to defer the adhibition of mercury till the diseased bone has fairly separated; when, however, the exfoliation is very tedious, it is not advisable to wait till it has taken place, before the mercury is commenced, but bearing in mind the possibility of a relapse, it will be judicious not to give the patient a positive assurance of his safety till five or six months after the separation of the dead bone.

Syphilis in Pregnant Women.—There is nothing very remarkable or requiring particular treatment when pregnant women are affected with lues. The course of its different stages takes place as under common circumstances.

When venereal blotches exist, they become liable to sore nipples, particularly during the latter months of pregnancy. In the first four months the free use of mercury is apt to produce abortion; it is therefore of importance to introduce it slowly. The warm bath also can be seldom borne without great inconvenience. Sometimes primary sores will remain stationary during the whole period of utero-gestation, but after delivery will yield and heal under the proper effect of mercury. On the other hand, pregnant women, under the proper use of mercury, have been apparently cured, but after delivery have suffered a relapse.

After the sixth month of utero-gestation the cure of syphilitic disease is very uncertain; primary symptoms may indeed sometimes be cured during this period,

but there is always an uncertainty attending such cases.

If a woman be imperfectly cured, and she conceive again, either the symptoms will remain stationary, or if apparently removed, the poison, not being eradicated, will lie dormant till after parturition, when the mercury will be again required. For example:—a woman went through a course of mercury during the latter part of pregnancy, and was not completely cured. She proved with child again, and there were no clear symptoms of the disease till after the birth of the second child, when secondary symptoms appeared on both mother and child.

(*To be continued.*)

EMPLOYMENT OF CHLOROFORM IN ACUTE TRAUMATIC TETANUS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Cases of tetanus and some other convulsive diseases are reported to have been successfully treated with chloroform. The following afforded an opportunity of testing this agent, the result of which I beg to forward for insertion:—

A lad, aged 17, employed as a sailor on board a trading vessel, accidentally placed his foot within a coil of chain cable, just as the anchor (weighing 6 cwt.) was let go. His leg was forcibly drawn to the windlass, and there held with a severe gripe, for two or three minutes. A fracture of both tibia and fibula, with laceration of the integuments covering the gastrocnemius muscle, was the consequence. The accident occurred early on the morning of the 19th instant. In the afternoon he was brought on shore and conveyed to the Lowestoft Infirmary. The limb was carefully placed in splints, and all went on favourably, until the morning of the 29th, when symptoms of tetanus were first manifested by slight difficulty of deglutition, and stiffness about the muscles of the neck, with quickened pulse. A large dose of calomel was prescribed, followed by turpentine and castor oil.

In the course of the day the nurse reported the bowels to have been freely operated upon, and that some liquid diet had been swallowed. Towards evening, the rigidity of the muscles of the neck increased, extending to those of the back, producing a tendency to opisthotonos, attended with spasms. Another dose of turpentine was administered, followed by an injection of the same ingredient mixed with castor oil, and a grain and a half of opium ordered every two or three hours. If these means failed to afford relief, a blister was directed to be applied to the whole length of the spinal column, and the injection to be repeated in the course of the night. These orders were entrusted to one of my pupils, who kindly remained with the patient all night.

I was at the bed-side of the patient early on the following morning, and was informed he had passed a disturbed night, and was scarcely able to swallow the smallest quantity of liquid. The spasms had become more severe, and were repeated every few minutes. Trismus was now complete, together with opisthotonos to a painful degree, and the countenance presented a frightful tetanic grin, expressive of much agony. During the paroxysms, the pulse rose to 160, respiration was performed in a forcible and convulsive manner, and the face was of a deep purple hue. Death from asphyxia seemed inevitable. The patient being completely lock-jawed, we were precluded administering further remedies by the mouth; it was therefore proposed to make trial of the chloroform.

A piece of sponge, containing two drachms, being introduced into the chamber of Coxeter's inhaler, an anæsthetic influence was speedily produced, and maintained, more or less, for a period of two hours and a half. The effect was striking; the muscles became so completely relaxed, that the head could with facility be bent forward, and the spine straightened. The masseter muscles lost their rigidity, so that by depressing the symphysis of the chin, the mouth could be opened to any extent. Respiration was performed with greater freedom; the pulse fell to 140; the countenance became less livid. An attempt was made to swallow one or two pieces of orange, and on questioning him how he felt, he replied, better.

The use of the chloroform was suspended for three quarters of an hour, when the spasms returned, and after two or three paroxysms, resumed their wonted activity. Inhalation was again had recourse to, and was followed by a mitigation of symptoms. It was persevered in at intervals until nearly five o'clock in the afternoon, when a frightful spasm took place, and the poor sufferer died asphyxiated, thirty-three hours from the commencement of the attack, and twelve days after the accident.

Upon a *post-mortem* examination, the abdominal viscera presented throughout a healthy appearance. The lungs were slightly congested, but retained their crepitancy. The lining membrane of the larynx exhibited an appearance of capillary injection, especially about the glottis, which assumed a crimson hue. The brain, with the spinal cord, was inspected, but no traces of structural alteration were discernable.

It may be remarked, that the above case affords an interesting example of the extent to which chloroform may be used, without apparently deteriorating the cerebral functions; for just previous to the fatal attack of spasm, the patient retained full possession of his mental faculties, and although we were disappointed in obtaining a curative effect, yet it was most gratifying to witness its palliative influence, at a time when I believe all other attempts at relief would not only have proved abortive, but, perhaps, aggravated the sufferings of the unfortunate patient.

I remain, Sir,

Your obedient servant,

W. C. WORTHINGTON, F.R.C.S.

Lowestoft, April 7, 1848.

CHLOROFORM IN CATALEPSY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

If the following is worth reporting, may I beg of you to introduce it into the *Provincial Medical and Surgical Journal.*

Your obedient Servant,

FRED. BAINBRIDGE.

Harrogate, March 23, 1848.

In the case of a female, aged 43, affected with catalepsy, whom I am now attending, I found the use of chloroform of infinite service, enabling me to administer medicine which was otherwise impracticable. This is the second time I have been consulted within the last three months. The first time I saw her was subsequent to the cataleptic state, but now it came on during my attendance, so that I had every opportunity of watching its progression and decline. When the cataleptic state was perfect, and had lasted for sixteen hours, after trying turpentine stimuli externally, and enemata, which proved of no avail, I presented the vapour of chloroform to her nostrils and mouth by means of a handkerchief. The fourth inspiration produced a change. Each inhalation, previously inaudible, now became prolonged and loud, as though the vapour gave great satisfaction. The pulse, which had been 56 was increased to 84; the iris gained its wonted power and sensation, and the limbs, with every voluntary muscle in the body, were now again obedient to the will. This being just what I wanted, I made her sit up and take some medicine, which could not be done before, on account of the existence of trismus. She soon again sank into her former state, but from that hour her recovery commenced.

CASE OF RETROVERSION OF THE UTERUS AT THE SIXTH MONTH OF PREGNANCY.

By J. SEDDON, M.D., F.R.C.S., Longdon, near Lichfield.

On the 25th of January, 1843, I was called by the surgeon in attendance to see Mrs. N——, aged 38, at that time in labour with her first child. She was a person of healthy appearance, well formed, and of capacious pelvis, and had been married seven years. Soon after her marriage she had experienced a miscarriage, since which she had menstruated at the regular periods, up to July, 1842. About the 19th of this month she had the usual appearance of catamenia, which ceased altogether after this period. About the beginning of September following, she had some derangement of stomach, and complained of difficulty in passing her water, but it does not appear that she had at any time complete retention of urine. At a later period she suffered from pains in the abdomen, which had become enlarged, but she was not satisfied of her pregnancy till about the end of November, when the movements of the child were felt by her. I found that she had experienced labour-pains at long intervals, for the last ten days, and that three days ago there had been a free discharge of liquor amnii.

On examination, I found the uterine tumour filling the cavity of the pelvis, and almost bearing on the perineum, but could not feel the os uteri. On a further examination, I managed to pass my fingers up along the vagina in front of the tumour, and behind the os pubis, but could not reach the os uteri, which seemed to be elevated above the pubis, the fundus resting in the pelvis.

The case appearing to be one of retroversio uteri, and the patient in the sixth month of pregnancy, we decided to attempt the replacement of the uterus. For this purpose our patient was placed on her knees, at the lower end of the bed, her hands resting on the floor. I then introduced my hand into the vagina, behind the tumour, and made pressure against it, but could not succeed in moving it out of the pelvis. Pressure on the tumour through the rectum had no better effect.

As our patient had no urgent symptoms, and the pains were not violent, and as she passed her urine freely, we decided to wait till the pains became stronger and more frequent, and then, if occasion required it, to endeavour to introduce the hand into the uterus, and bring down the fœtus. An opiate was to be given occasionally, and the bowels kept regular by castor oil and injections.

On the 29th of January, the pains having become urgent, and a portion of the umbilical cord having passed through the os externum, there being no pulsation in the cord, it was decided at once to attempt the delivery. With some difficulty I introduced my hand up the vagina, behind the os pubis, and by perseverance succeeded in passing it through the os uteri, when one of the feet, which presented, was felt and brought down, and the delivery of the fœtus easily completed. After waiting some time, the hand was again introduced, and the placenta brought away. This operation, however was not very easily effected, as the vagina and uterus formed an acute angle with each other, and the placenta attached to the fundus uteri, which still remained low in the pelvis, was reached with difficulty. A gentle attempt was now made to replace the uterus, but without success.

The first few days after delivery the patient had some pain and tension of the abdomen, which were easily subdued, and she slowly recovered her accustomed health.

Seven weeks after the confinement an examination was made, and the uterus found still retroverted. An attempt was again made to put it in its proper position, which proved unsuccessful. I did not make use of the uterine sound at this time, because I was not acquainted with its invention and application to displacements of the uterus, though I had previously made use of the flexible metallic catheter to explore the uterus, in suspected disease of that organ. Whether the sound would have been successful in this case or not, remains a conjecture. I am, however, inclined to the opinion, that the displacement might have existed for a long time, and the organ become accommodated to its

altered position, thus rendering its adjustment the more difficult. This case, perhaps, may possess some additional interest, inasmuch as it shows that the hand (a small one at least,) may be introduced with safety into the uterus at the sixth month of pregnancy, for the purpose of delivery.

CLINICAL NOTES FROM PRIVATE PRACTICE.

By W. H. Ranking, M.D., Norwich.

The object of the present series of communications, is to place on record some of those more interesting cases of disease, which the physician actually engaged in practice occasionally meets with, and which, although in their isolated position of comparatively little value, allowing of at best but the most cautious deductions as regards *principles* of treatment, yet may by their accumulation at some time or other be subservient to the purposes of generalization. The series will not be continued uninterruptedly, but we shall in a measure be guided in the publication of cases by the non-occupation of the pages of this Journal by better or more pressing matter.

1. *Obstinate Intercostal Neuralgia: Failure of Quinine, Iron, Colchicum, Arsenic, &c.: Permanent Cure by Electro-Magnetism.*

J. S., a tailor of this city, in extensive business, consulted me in June of last year. From his surgeon I elicited the following history:—

Eighteen months since, while indulging in his favourite pastime of yachting, he was suddenly seized with excruciating pain on each side of the thorax in front, and at a point corresponding with the union of the cartilages with the ninth ribs. This pain was periodic in its access as long as it lasted, which varied from one to three weeks, and had recurred several times at indeterminate intervals. It was always found to be relieved by a grain of morphine, and the patient was generally free from it the next day, though suffering severely from nausea and giddiness, the result of the narcotic. At the same hour, however, on the third day, it did not fail to reappear, to be again subdued by the opiate.

One or two physicians had previously been consulted, and they had, as far as I can ascertain, regarded the pain as symptomatic of gall-stone, or renal calculus. No relief, however, had been obtained beyond that afforded by the morphine, and the patient had resigned himself to the impression that his disease was irremediable, when his medical attendant requested me to prescribe for him.

At the time of my first visit, June 24th, at 11 p.m., the patient was in bed with the paroxysm in full force. The pain was so agonizing that he was almost maniacal, rolling upon the bed, tearing his hair out by handfuls, and even threatening suicide unless he was relieved. The pain was exactly confined to the two spots above mentioned, and could on each side be covered by the tip of the finger. It was described as a "burning tearing pain." In spite of the suffering, the pulse was 60, and there was no heat of skin, beyond what might be induced by his violent agitation. There was no vomiting, no jaundice, no retraction of the testicle, no suppression of urine. The abdomen bore pressure in every direction. No spinal tenderness was present, nor pain external to the ribs beneath which the pain was described to be seated.

The habits of the patient were not of the quietest order; he was extremely fond of boating, and indulged freely in beer and tobacco, consequently he had symptoms of irritative dyspepsia. There was no ascertainable gouty or syphilitic taint.

The emergency of the symptoms left no choice of medicine, and he accordingly took his usual dose of morphine, which in the space of a couple of hours left him tranquil.

The next day (25th,) the pain had quite subsided; complained only of the effects of morphia. Rigid diet.

26th. Has remained free from pain till about 7 p.m., when it recurred with full force, and was quieted as before. Ordered Quininæ, gr. vj.; Zinci Sulph., gr. j., every four hours. A small blister to be applied over each painful spot, and to be dressed with savine ointment every four hours, each dressing to contain one grain of morphine.

By this means the pain was kept in abeyance for three days, when, thinking himself better, the endermic use of morphine was omitted. The amendment proved, however, but temporary; in less than a week it reappeared, with its accustomed tertian character, and equal severity.

It would be uninteresting to follow this case through all its details; suffice it to say, that quinine was at length given up for iron; this in its turn for colchicum; this for arsenic. Then various combinations of each were tried, but to no purpose. Æther was exhibited on several occasions during the paroxysm, but although its anæsthetic effects were fully produced, the pain returned with returning consciousness.

Under these circumstances I determined to give little or no medicine, merely bismuth and rhubarb, and to have recourse to electro-magnetism. This agent was operated with every day during twenty minutes, and a few days only had elapsed when decided benefit was declared. The intervals between the paroxysms were prolonged, and the pain gradually became so tolerable, that the patient was able to dispense with his morphine. In the course of a month it had entirely left him, and to this time (near eight months,) he has not had the slightest return.

I regard the above case as interesting, as exhibiting, in a very distinct manner, the therapeutic powers of electro-magnetism. The case had previously exhausted the patience, both of patient and physician, and had been assailed by almost every remedy in the pharmacopœia.

It was judged to be intercostal neuralgia, from the absence of febrile disturbance, the want of evidence of gall-stone, or renal calculus, and more especially by the exactly symmetrical locality of the pain.

The instrument employed was that recommended

by Dr. Golding Bird. The current was passed through the arms first, for a space of twenty minutes, the patient holding a conductor in each hand. It was subsequently made to traverse the intercostal nerves, by placing one conductor over the spine, and the other alternately over the painful spots. The tension was preserved as high as it could be borne.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, APRIL 19, 1848.

The subjoined memorial to the Royal College of Physicians is grounded upon the representations of those gentlemen practising as physicians in the provinces, who have favoured the Council with replies to the notice inserted in this Journal of the 8th of March last. The memorial has been forwarded to Dr. Hawkins, the Registrar of the College, for the consideration of the College authorities, and we believe that the members of the Association who are interested in the question, and provincial physicians in general, may feel assured, not only that the representations of the Council will meet with attention, but, as we have every reason to think, that the College is disposed to act with all fairness and liberality in regard to the provisions of the new Charter:—

To the President and Fellows of the Royal College of Physicians.

The Council of the Provincial Medical and Surgical Association having taken into consideration the clauses 4 and 5 of the proposed Charter of the Royal College of Physicians of England, as printed in the Report of the Select Committee of the House of Commons, bearing date the sixteenth day of July, 1847, and also the objections which have been severally made to the above clauses by Graduates of British Uuniversities, and others, practising as Physicians in this country, beg leave respectfully to offer the following suggestions to the President and Fellows of the Royal College of Physicians, in reference to these clauses.

1. That a diploma conferring the degree of Doctor of Medicine from any British University, and bearing date prior to the first day of January, 1848, should be received as sufficient qualification, without further examination, for admission to the Royal College of Physicians of England, as an Associate or Member under the new Charter.

2. That the candidates should be required to be of the age of twenty-six years or upwards, at the time of admission, instead of thirty years, as stated in clause 5 of the proposed Charter.

3. That the amount of the entrance fee should be fixed at ten guineas instead of twenty-five guineas.

4. That considering that the Extra-Licentiates of the College had duly complied with the regulations of the College Charter, at the time of their receiving the license of the College to practise as physicians *extra urbem*, and their right to do so being now recognized by law, it would be unjust to deprive them of such right by any retrospective measure, and that therefore such of those gentlemen admitted Extra-Licentiates prior to the first day of January, 1848, as shall be practising as physicians only, at the time of the granting of the new Charter, should be admitted Associates or Members of the College, without further examination.

5. That in all cases of admission to the new order of Associates, or Members, whether of the existing Licentiates of the College, the Graduates of British Universities practising as physicians in the country, or the Extra-Licentiates, testimonials of moral character and general professional conduct should be required.

6. That gentlemen possessing the degree of Doctor in Medicine from any British University, bearing date prior to the first day of January, 1848, but now in general practice, may be hereafter entitled, on retiring from such practice, and being of the age of —— years, to present themselves for admission as Associates or Members of the College; and that such gentlemen, on producing sufficient testimonials of character and professional qualification, shall be admitted Associates or Members without further examination, on payment of an entrance fee of —— guineas, exclusive of stamp duty.

7. The Council of the Provincial Medical and Surgical Association would further recommend to the consideration of the Royal College of Physicians, the propriety of introducing some clause providing for the reception into the College of such gentlemen now practising as physicians, as may have taken the degree of Doctor in Medicine in Foreign Universities of reputation, after having undergone a sufficient course of study, and submitted to regular examination therein.

8. That the Fellows of the Royal College of

Physicians of Edinburgh and Dublin, who may be practising as physicians in England at the time of the granting of the new Charter, be also entitled to become Associates or Members of the Royal College of Physicians of England, under the same provisions as those regulating the admission of Graduates of British Universities.

Reviews.

Researches into the Pathology and Treatment of the Asiatic or Algide Cholera. By E. A. PARKES, M.D., Lond., Assistant Physician to University College Hospital. London. 1847. 8vo.. pp. 250.

A Disquisition on Pestilential Cholera; being an Attempt to explain its Phenomena, Nature, Cause, Prevention, and Treatment, by Reference to an Extrinsic Fungous Origin. By CHARLES COWDELL, M.B., M.R.C.S. London. 1848. 8vo. pp. 210.

There are many questions of deep interest connected with the study of the Asiatic, Epidemic, or Algide Cholera, which, when the energies of the physician, during a period when the disease is actually prevalent, are tested to the utmost by the requirements of practice, are not readily capable of solution. The necessity which then exists for the most assiduous and unremitting attention being given to the treatment of individual cases; the harass and distraction of mind produced by imperative calls for assistance which everywhere meet the physician, and the deprivation of natural rest which ensues from very many of these being made in the night, tend greatly to interfere with that calm investigation which is so all-important for the elucidation of truth. It is, then, of deep importance, that the points to which inquiry should be especially directed be well thought of before hand, and that the best manner in which observations are to be made, be accurately determined; that when the time comes in which only such points can be satisfactorily determined, the attention of all who are placed in circumstances favourable for observation, may at once be called forth, and their inquiries directed into the proper channel.

Among the points on which information is especially required, are the causes which generate the disease,—the conditions which favour its progress,—its actual nature or essence,—and, lastly, the preventive and remedial measures most fitted to check its progress, and to control its effects, whether among the community, or in the individual. Our subsequent remarks will be chiefly directed to certain subjects of interest which we find elucidated in the works before us.

The work of Dr. Parkes is altogether one of great excellence, as being derived from careful personal observation and study of the disease, and considered as a guide to what is already known, or as clearly marking out the direction in which further researches are required, it is well worthy of attentive perusal. The "leading idea" which the author has formed of the nature of cholera, is "not only that it is primarily a disease of the blood, as has been so generally surmised, but that the changes induced in the function of respiration, directly consequent on the alteration of the blood, are the proper and distinctive symptoms of the disease."—p. 4. This idea receives ample illustration in various parts of his treatise, especially those in which the symptoms are described, but as the general and essential characters of cholera are, it is to be presumed, sufficiently familiar, either from personal experience, or from the description of the many able writers on the subject, it is unnecessary here to do more than to indicate the conclusion at which Dr. Parkes has arrived, most of our readers having the means of forming their own judgment as to its general correctness and agreement with recorded facts.

A careful description of the pathological appearances observed after death is given by the author, drawn up from forty-six dissections in males, and from these we extract, as bearing especially on the "leading idea" above quoted, the changes observed in the blood, those noticed in the organs of circulation, and these in the lungs. 1st. We are informed, "It appeared probable, from all the observations, that there was a deficiency of fibrin, or a great tendency to the separation and deposition of this ingredient; that albumen and salts were present in undetermined quantity; and that the red particles were sometimes partly dissolved in the serum, but not in other cases appreciably altered in figure and appearance."—p. 34. 2nd. "The right side of the heart and the pulmonary arteries were generally filled, and, in some cases, distended with blood; the left side and aorta were generally empty, or contained only a small quantity of dark blood. The inference which was drawn from the state of the cavities, in the greater number of cases, was, that the right side had continued to receive blood till, in some cases, it became full and even distended, while the left side had received little or no blood, but had continued to contract, in some cases even violently, on the last drop of blood which had entered it."—p. 23. 3rd. "The most common appearances in the lungs are, the presence of blood in the large vessels chiefly or solely; the collapse, and the deficient crepitation, arising from the more or less complete absence of air and blood, and from the approximation from some unknown cause of the molecules of the pulmonary substance. In other cases there is more blood in the minute structure, a

corresponding dark colour of the lung, and a variable amount of frothy serum; the quantity of frothy serum bears an inverse ratio to the degree of collapse."—p. 20.

We have here given only the condensed summaries of the results arrived at, but to obtain a just conception of the entire bearing of the facts on the author's views, or on the actual pathology, it is necessary to refer to the observations more in detail:—thus, fibrinous coagula were noticed in several cases in the heart, chiefly in the cavities on the right side; the blood, whether coagulated or not, had usually a dark colour; the serum removed from the heart when large coagula were present in its cavities, was dark-coloured and thick, depositing a loose cloud of colouring matter on standing some hours, and the supernatant portion was seldom colourless, some hæmatosine appearing to be dissolved in it. Under the microscope also, though no alteration was observed in the form of the red particles, they seemed in some cases to have partially lost their power of running together, and applying themselves side to side.—pp. 31 to 34.

Whether these changes in the blood are to be considered as an early or more remote effect of the action of the morbific poison, does not clearly appear; the blood would seem, however, to be ultimately arrested in its course in the lungs, while the symptoms observed during the algide stage clearly evidence imperfect oxygenation to be an important element in the chain of events.

The main subjects for investigation, then, indicated in this direction, are the first impression of the external efficient cause on the system, the precise nature of this cause, its mode of ingress or attack, and the nature of the change which it produces. The microscope and minute chemical analysis must be the means of research employed in this investigation; and if, as would seem probable, the blood is truly the recipient of a peculiar zymotic leaven, and the medium through which its poisonous effects are exploded on the entire system, we may possibly hope, by the skilful employ- of these means, to obtain some insight into its actual nature.

In Dr. Cowdell's work this problem is attempted to be solved, and he brings forward many ingenious arguments to shew that the essential cause of the disease,—the *materies morbi*,—is to be sought for in the diffusion through the atmosphere of the sporules of some plant belonging to the fungi. His opinion is, that the cause of pestilential cholera is "a minute fungus, probably resembling the Torula Cerevisiæ;" (found in yeast, and presumed to be the source of the fermenting properties of that fluid;) that the germs of some such fungus "are absorbed through the lungs into the blood of bio-chemically (electrically) predisposed persons; that a process of germination, and consequent catalytic fermentation, is immediately established; the composition of the blood instantly begins to undergo a change, the heart is less stimulated by blood insufficiently, oxygenated, and nutrition—and consequently the extrication of animal heat—is checked throughout the capillary circulation; and coldness and lividity are thus produced."—p. 202.

It is unnecessary to pursue the subject further; in its present state the question of the fungous origin of the disease is purely hypothetical, but the hypothesis is very ingeniously supported by many analogical and well ascertained facts, for which Dr Cowdell's work may be consulted with advantage. The fungoid or vegetable nature of many diseases has been satisfactorily ascertained of late years; Dr. Cowdell's essay contains much information on this subject, which will be read with interest, independent of any presumed bearing which these views may have on the origin of cholera from a like source.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

COMMUNICATIONS.

[The following communications have been forwarded by Mr. Crompton.]

From Benjamin Barrow, Esq., of Bath, Fellow of the Royal Medico-Chirurgical Society of London, and late House-Surgeon to St. Bartholomew's Hospital.

In accordance with a direct request from my friend Mr. Crompton, I have collected together the following observations upon burns, which I have from time to time, during the last eighteen years, made in my note books, and these I now beg to present for the consideration of the readers of the *Provincial Medical and Surgical Journal*. The greater part were made during my connection with St. Bartholomew's Hospital, which was for a period of ten years; they may therefore, I think, be taken as a fair index of the result of treatment there employed. I shall only speak of those *remedies* which I have actually applied, and the effects of which I have watched *throughout in many cases*; there are *many* which I have never tried, having been satisfied with the efficacy of those hereinafter mentioned, but I would not be understood to imply that I am *wedded to them*, and should the evidence of the majority of those who may add their testimony upon the subject shew that any *decided advantage* accrues from any other mode, I shall be only too happy to bow to their decision, and to give their recommendation a fair trial; and this is, I trust, the spirit in which all will view the present enquiry, without which there can no good arise from its prosecution. Every thing connected with these accidents must be a matter of so much interest to all, that I shall venture to occupy a brief space with the history of the causes, nature, and severity of those cases of burns which are generally admitted into hospitals, and which present such

frightfully formidable appearances as are rarely met with from other calamities, and are so often attended, when life is saved, with almost irremediable deformities.

The *cause* of a very large majority of these accidents, I have no doubt, may be attributed to the unavoidable absence from home of those poor parents who have no other means of ensuring the safety of their children than by locking them up, and by confiding the care of one infant to that of another of almost equally tender age, unless they abandoned their only resource of providing daily bread for their already half-starved offspring and themselves. Upon this point I can speak very confidently, having always taken especial pains to learn the manner in which the accidents occurred, and lamentable indeed is it to reflect that so large a majority have their origin from the cause just mentioned.

If this point requires any further confirmation, we have it in the report of the Registrar General, in his letter to the coroners of the country, in the second part of his report for the year 1845, and from which I extract, that whilst only 3305 persons were killed in one year by every kind of mechanical injury, in the same period 3057 were lost by fire, (*i.e.*, 148 by explosions, 2577 by burns, and 332 by scalds,) and upon analysing the 2909 deaths by burns and scalds, there were of—

Males between the ages of 5 and 10.....	275
,, under the age of 5	799
Total	1074
Females between the ages of 5 and 10.....	528
,, under the age of 5	672
Total	1200
Total Males and Females under 10 years of age	2274

leaving the small proportion of 635 for both sexes above the age of 10.

The *severity* and *nature* are proved by the number of deaths which follow these accidents, and which might well astound those not conversant with them in large numbers, but which need no longer be matter of surprise, when we feel that the severity of these burns may be summed up by saying that the sufferers present more the appearance of having been roasted than any thing else to which we can compare them, all those portions of their persons being burnt which had previously the benefit of clothing, the fire only ceasing its raging when it had consumed all the fuel. Here, then, we have deep and extensive destruction of the life of a considerable portion of skin, involving the subcutaneous tissues, and including, in many cases, the muscular structures; the dusky yellow colour and total insensibility of the parts, shewing, alas! but too plainly, that sloughing to a great extent is inevitable, provided we can recover our patient from the state of perfect collapse in which we find him. These are some of the appalling accidents to which so many infants are unavoidably subject, and which might be brought forward as a forcible argument (if any be required,) for the necessity of numerous and well-regulated pauper-schools, which would be a sure means of preventing much human suffering and deformity.

The treatment I shall divide into the external or local applications, and into the internal or medicinal remedies.

Of the cases treated at St. Bartholomew's Hospital, the majority were seen almost immediately after the receipt of the injury, and before any remedies had been applied, the unfortunate sufferers being generally brought to the hospital wrapped in a blanket, if such a luxury belonged to the parents, if not, then in the apron or gown of the mother,—the necessary exposure for some time to the cold air, and the consequent increased depression of the vital powers, lessening of course the chances of recovery, and even of rallying from the state of collapse into which the sufferer is thrown.

The treatment usually adopted at the Hospital, and which I have since followed, is that proposed by Dr. Kentish; the mode of applying the dressings was by spreading upon linen the preparation of turpentine and wax, and placing it cold over every portion of the burnt surface, being careful to exclude *all* air. These dressings were renewed every third or fourth day, or more or less frequently, according to circumstances, the circumstances looked to being the comfort of the patient, and the discharge consequent upon the amount of sloughing, whether offensive or not. The dressings of turpentine were sometimes continued until healthy granulations appeared; in other cases, if the sloughing went on tardily, poultices of bread alone, or of linseed meal and bread, were substituted, and ultimately simple cerate, spread on lint; and I have sometimes at this stage of the cure kept cold-water dressings constantly applied, and with decided advantage. If the *granulations* shoot up too exuberantly, the application of nitrate of silver, either in solution or otherwise, was resorted to; if, on the other hand, they were flabby and unhealthy, requiring slightly stimulating, I know no better means than by sprinkling a sufficient quantity of the powder commonly termed red precipitate, over the surface, this is so easily managed, and so speedily efficacious. The turpentine dressings were of a decidedly soothing character, and were always attended with permanent relief to the patient, the amount of relief naturally varying in persons of different temperaments.

I would here observe, that I always superintended any changes of dressing, for I am quite certain that nurses, whether in or out of hospitals, are neither sufficiently cautious in protecting the raw surface from exposure to the air, nor in excluding air from beneath the dressings; and that these are the first and chief principles to be attended to in cases of burns, strange to say, there is no difference of opinion.

The treatment of covering the whole burnt surface thickly with flour, and repeating it whenever it becomes saturated with discharge, I have, upon several occasions, adopted, but I cannot say with that marked success which many record. In minor cases it has a soothing influence, but in those where there is extensive destruction of skin, it has two very decided drawbacks,—the first being the difficulty of keeping the parts clean and free from offensive discharge, for when sloughing has once set in, it is impossible to cleanse the parts without much pain to

the patient, and long exposure to the air; the second drawback being the irritation caused as soon as the flour cakes, irritation so excessive, that I have been obliged, on several occasions, to remove the dressing of flour, at least as far as practicable. These circumstances are, I conceive, quite sufficient to prevent the application of flour being adopted as a general rule in cases of burns, but I must not omit to mention where and when I have found the flour of advantage, and this has been when the injury has extended into almost every region of the body, and into those situations where it is impossible either to place, or to keep constantly applied, wool and other dressings. The first of the objections which I have named to the employment of flour, also applies, to a certain extent, to that of wool, as a *direct application*, although I am inclined, from the experience I have had, to give this a decided preference, as having a more marked soothing influence, both immediately after the receipt of the injury, and during the processes which follow. That this influence is due to the softness of the wool, forming as it does a cushion for the injured parts and exposed nerves to rest on, is quite clear. After close and long observation, I have come to the conclusion—a conclusion founded on facts—that the most efficacious remedy as a *direct* and *immediate* application to the burnt surface, is the turpentine dressing; but not alone, for I have combined with this in one and the same case, wool or wadding, (such as ladies put in their dresses,) winding round the first dressing several layers of this, giving thereby the greatest ease to the patient, and to this plan I would beg to direct the attention and serious consideration of all who may have to treat cases of burns or scalds. Care must be taken when wool or wadding is applied, that all portions which become too tense or too loose, be released or tightened, according to circumstances, and in all cases the greatest attention is necessary to avoid anything like a ligature around any portion of the body or limbs.

The late Mr. Earle was accustomed, in burns of a minor description, to apply cold water, by keeping the parts constantly covered with cloths saturated with the pure element. I had an opportunity of witnessing a tolerably extensive trial of this remedy, but I cannot speak of it as possessing any decidedly efficacious properties. There was a certain amount of comfort experienced for a time, but for a very limited extent, and I think the subsequent inflammation and sloughing were generally increased.

In minor burns and scalds, in which the cuticle is only raised into blisters, or in which the injury to the deeper parts is very slight, after allowing the fluid to escape from the bladders thus formed, a poultice of potato and bread, finely grated, and mixed in equal parts, is as good and as simple a remedy as can be found; but even in these cases I strongly advise that the poultice should be prepared ready for application, before pricking the blistered surface, in order to exclude, as far as practicable, the external air, the sudden admission of which I have, upon more than one occasion, seen to produce pain so intense, as to induce a state of almost complete prostration. As regards the application of ordinary poultices, in the second or any stage of burns, should the suffering be great, I always recommend that they should be made with the tincture of opium and water, and applied either warm or cold, according to the feelings of the patient, the proportions, as I have used them, being from half a drachm to one drachm of the tincture, to an ounce of water.

The *medicinal* or *internal* remedies, as stimulants, must of course in a great measure, be regulated by the age and strength, the habits and constitution of the patient, by the state in which we find him, or by that into which he may fall. For children, I have generally found the most satisfactory quietus to be from five to ten or more drops of laudanum on a lump of sugar, or the same quantity mixed from time to time with moist sugar or treacle, and spread on bread, which they eat with great gusto; for adults, one or two drachms or more may be requisite for a dose, and frequently repeated according to the state of the nervous system. The stimulants are brandy or gin and water, the latter is generally best, for, unfortunately, the majority of patients, of whatever age, have been from their birth accustomed to this beverage. Æther and ammonia may also at times be useful additions; the compound tincture of camphor is also a desirable remedy, especially for children. Diuretics are in many cases urgently called for, the urine being often deficient in quantity, and not unfrequently altogether suppressed, a consequence not to be wondered at, knowing as we do, the occasional effects of an ordinary blister.

In the administration of sedatives, and diffusive stimulants, the greatest caution is requisite, in neither continuing them too long, nor in abandoning them too soon. In connection with them the application of hot bricks or bottles, with any other available means for producing warmth, must not be overlooked. The necessity for continuing or abandoning these various remedies, must be regulated by the pulse, the state of the skin, and the respiration, which last is, I consider, a point requiring a word or two of especial notice, and to which it has often struck me, far too little attention has been paid. The breathing is, as all must have observed, most frequently in these cases laborious and hurried, caused for the most part by exhaustion, and it is interesting to watch how quiet it becomes, as the pulse gradually regains its power and the system recovers from the first shock of the accident. I would lay some stress upon this symptom, for I have upon more than one occasion heard doubts expressed, whether the patient would not die from suffocation, and I have also seen stimulants refused at a time when they would have been *most beneficial*, for fear of increasing inflammation to which this laborious and hurried breathing was attributed. Vomiting is a symptom very frequently present in these cases, and one which causes considerable distress to the patient, no less than embarassment to the medical attendant, continuing in spite of all the usual remedies. That which proves in the largest number efficacious, is opium, in doses from half a grain to a grain, or even more may be required in some individuals. Thirst is often excessive, and when the stomach is thus irritable it

becomes a matter of difficulty to decide upon the fluid most likely to agree; that which I recommend and have found most generally beneficial, is soda water and milk, and this has the double advantage of being both refreshing and nourishing. The administration of purgatives in these cases has been long and is still a matter of some controversy; no observations, therefore, upon the subject of burns, would be complete without an opinion, and which I now offer with much caution and deference. To lay down any decided rule upon this head is, I am sure, quite impossible, for I have as often seen diarrhœa as constipation in these cases. If the former be present or arise, it ought to be stopped as speedily as possible, for if allowed to continue it only tends further to reduce the vital powers of our patient. If the latter, I am always quite satisfied for the bowels to remain quiet for a day or two, until the powers of the patient have rallied, and they are better able to bear the action of medicine; when this is given it must be with great caution, all drastic purgatives being avoided. The medicine which I recommend and have found most efficacious, is castor oil with some drops of laudanum, the quantity of both being regulated by circumstances. As regards diarrhœa, I would here observe that I have frequently seen that which Mr. Wood, of Rochdale, has mentioned, viz., that sloughing being over, the healing process going on to all appearance most favourably, at the end of a month or longer an attack of diarrhœa supervenes, which if it does not destroy the patient, retards his recovery, and places his life in imminent danger. I am inclined to attribute this diarrhœa to the overloading of the stomach and bowels with nourishment to which the system has been previously totally unaccustomed, and thus by carrying nutrition too far, we are actually causing death by the very means which we believe to be life to the patient.

The period at which death occurs varies so much that no data or inferences can be drawn from this result. I find from the cases which I have on record, and from which I have drawn the foregoing conclusions, that death may happen from the first to the ninth or eleventh day; if patients outlive this period we may entertain hopes of their recovery, bearing in mind the untoward occurrence of diarrhœa to which I have referred, and which must always make us guarded in our expressions of hope to the parents and friends of the sufferer. The *post-mortem* examinations of some fifty cases which I have made, although they have discovered either a congested state of lung or brain, with some slight effusion, or intestinal derangement, such as enlargement of the mesenteric glands, with traces of old or recent inflammation, still, I have scarcely ever seen any *decided* lesion to which to attribute the sudden, and in many cases, unexpected death of a patient. All who have been attached to a large hospital, or connected with mines, and other places in which a large number of these accidents occur, must have been struck by these sudden deaths, and for which, upon *post-mortem* examinations, no account can be given. I have read with attention the careful and laborious observations of Mr. Erichsen, but am unable to accord in the view he has taken of the causes of death in the cases of burns, for I believe the various morbid appearances which are discovered, and to which he attributes death, to arise from a very different influence than that of the recent injury; for I do not think that upon minute examination, these lesions, taken either alone or together, (of course I speak in the majority of cases,) are of a sufficiently urgent and severe character to account for death. By reference to the registration of deaths one cannot but be struck with the immense majority occurring before the age of ten years, from affections of the bowels, brain, and respiratory organs, and it is before this age (as I have before shown,) that a very large proportion of burns take place, and in a class of individuals whose constitutions we must admit to have been, previously to any recent injury, more or less impaired by the deficiency, as well as by the inferior quality, of food and drink upon which life has been sustained. Bearing in mind these circumstances, I do not think we need travel far to account for the lesions of the stomach and intestines; for those of the brain and lungs we may account by recalling to memory the constant supply of stimulants and sedatives, administered both before and after the injury, as also to the position in which the body is often carried and placed immediately after death; and this last is a point which I believe is too often overlooked in *post-mortem* examinations.

These are (as far as I have from time to time noted down,) the chief points connected with the cause, the treatment, both local and general, the symptoms and results, and the *post-mortem* appearances of cases of burns.

I now turn to those cases which survive the injury, and in which the healing process follows,—a process in the management of which the *greatest care* is necessary, in order to prevent those frightful contractions which so often take place, in spite of our utmost endeavours to avoid them. The healing of the sores caused by burns is, under any circumstances, and in all regions of the body, a most tedious process, but most so when the parts have sloughed in the neighbourhood of the tendons and fasciæ, the granulations springing up but tardily in these situations, as might naturally be expected. When the burn is very extensive, occupying the whole surface of the arm or leg, it is most difficult to counteract the inclination to contract either at the elbow or knee-joint, for any confinement by means of mechanical agents is attended with so much suffering as almost entirely to preclude their use. The only method of effecting this is, I have found, by completely covering pieces of pasteboard or wooden splints with as much wool or other soft material as will form a pad, the external layer being the application desired as the remedy. We must not be satisfied with one splint, nor with a short one, but must employ at any rate two, and those of sufficient length—that is, one above and one beneath the joint, at the same time taking the greatest care to fill up the lateral spaces with the same soft material, and to bring them to a level with the upper and lower coverings; otherwise the bandages, which are applied to keep the splints *in situ*, will act as ligatures,

and thereby cause so much uneasiness as to compel the early abandonment of these necessary precautions against contraction. Another point to be carefully attended to, is to keep the splint on long enough, for even after the wound has healed, as the cicatrix hardens, so will the parts become gradually contracted, unless the limb is kept firmly extended. When these contractions about the joints have taken place, I know no better plan of overcoming them than that to which I drew attention, when giving a description of my joint-splint in an early number of the Journal for last year, and which I here again beg to recal to mind, by relating a case, which elucidates my meaning better than any other mode:—

"A little girl, aged 8 years, was brought to me on account of a contraction at the bend of the elbow-joint, and which, upon enquiry, I learnt had occurred nearly five years previously, following a rather severe burn, in which the sloughing had penetrated deeply; that, as the wound healed, so the arm became bent; that the cicatrix had been twice divided, and that on the last occasion a portion of the hardened skin had been removed; that considerable difficulty had been after each operation experienced in keeping the arm extended during the progress of the healing of the wound; and that a common straight splint, which had been fixed on the back of the arm, had caused so much pain and uneasiness as to oblige its removal, and, as a consequence, the present deformity. I placed upon the arm my apparatus, and with a scalpel just slightly divided the cicatrix upon the first day, placing the arm at the angle which this division allowed, without causing pain, and there fixed it by means of the joint-splint. Two days subsequently I again divided the cicatrix, again altered the angle of the arm, and at the same time the splint. This operation I repeated at five different periods, at about three days' interval, and at each time placed the arm and splint at the angle, which I found compatible with the child's comfort. The arm had become perfectly straight in about six weeks; the splint was, however, still retained upon the limb, the straight position being occasionally changed for an angle more or less acute as the fancy took me, thus avoiding the chance of tiring my patient, or of the arm becoming stiff. During the latter period friction and fomentations were frequently employed, whereby the cicatrized skin in a great measure regained its natural condition. The arm in about three months was equal in usefulness to that of its fellow."

It is unnecessary for me to dilate upon the various operations proposed and performed for the cure of these contractions, many of which I have witnessed, and some myself done, but from which comparatively little good has resulted, especially when they have been for the relief of those contractions and hardened cicatrices which bind down the chin to the sternum, or confine the arm, close in the axilla, to the side. To avoid these I would recommend, that immediately granulation commences, a pad, in the shape of a horse collar, be formed of soft material, and placed between the healing surfaces, the external layer being, as in the case of splints before mentioned, the medicinal remedy we desire. This pad can be easily retained *in situ*, and if well made will be a comfortable resting place for the patient's chin, and if the occasion requires it between the arm and side, it can be with equal facility and comfort applied.

Before dismissing the subject of operation in cases of contractions, I would venture to offer a word of caution to any young aspirant after operative fame, and who may not have seen many of these attempts to relieve deformity, for he will be sadly disappointed at the result, and not a little astonished at the depth to which he must cut, if he expects in any way to relieve his patient. Of all operations these are the most tedious, and the most unsatisfactory, besides being most acutely painful.

Thus have I endeavoured to fulfil, conscientiously, the request made by Mr. Crompton, that I would give him in full the result of my experience in cases of burns; I fear that I have extended my observations almost beyond reasonable limits, but I was unwilling to reply to the queries proposed without giving my grounds for the answers, and which I now venture to append as a summary of the foregoing remarks:—

1. Stimulants in the form of turpentine and wax dressings, and applied cold.

2. Attended with no decided beneficial result; likely to increase inflammation and sloughing.

3. Cotton and flour are to a certain extent applicable and beneficial, but only as adjuncts to the stimulating remedies.

4. Diffusive stimulants and sedatives carefully regulated.

5. Extent of course affects the result, but I do not think situation has much to do with it.

6. Careful suppression of granulations, when they spring up too exuberantly.

7. Slight congestion of lungs and brain, with effusion sometimes, and some intestinal derangement.

8. Doubtful; dependent upon the extent of burn, and the previous account of patient's health and strength.

9. Gradual division, and careful adaptation of splints and pads, according to situation.

10. For the poor to send their children to school, and to exclude all air with the most available covering.

11. See the foregoing remarks.

12. These, as before stated, occur at the time when sloughing has finished, and the healing processes are going on.

Foreign Department.

CLINICAL MEDICINE AND SURGERY IN THE CONTINENTAL HOSPITALS.

[Under this head we purpose at appropriate times to lay before the readers of the *Provincial Journal*, an abstract of the most important clinical lectures, delivered at the different foreign hospitals, premising that as our space is limited, our selections will be confined to

those lectures which offer points of more than ordinary practical interest.]

1. *Volvulus or Intestinal Invagination.*—This is so formidable a lesion, that every new example becomes worthy of attention. The following occurred in the practice of M. Chomel:—

A young scrofulous female, aged 19, was admitted into the Hotel Dieu, with symptoms of intestinal obstruction, which had appeared suddenly eight days previously. She vomited incessantly; the abdomen was tympanitic; the face hypocratic; feebleness extreme; pulse 134. The abdomen was painful and dull on percussion over its lower two-thirds, indicating peritoneal effusion. Neither examination per rectum, nor of the vomited matter, threw any light on the nature of the obstruction. No tumour nor inequality was perceptible in the abdominal cavity. Whatever its nature, M. Chomel had no difficulty in diagnosticating *intestinal obstruction*; he could not, however, decide whether it was a case of invagination, ileus, or internal strangulation. The great debility of the patient precluded blood-letting, and M. Chomel therefore ordered bladders of ice to the abdomen, finely-powdered ice internally to be swallowed before it could melt in the mouth, and every hour one of the following pills:—Resin of scammony, 18 grains, croton oil, 4 drops, into ten pills. Repeated cold enemata were also exhibited.

Upon this case M. Chomel commented as follows:—Not being able to define the exact nature of the obstruction, he stated that he used the general term intestinal occlusion, although he leant to the opinion that it was a case of invagination. The term invagination, he stated to be synonymous with intus-susception, whereas *volvulus* signified the twisting of a loop of bowel upon itself, and consequent strangulation at the point of crossing. The term *ileus* he applies to obstruction from inflammatory spasm of the intestine. Internal strangulation supposes the engagement of a portion of bowel under a constricting band. Many writers class all these varieties of occlusion under the term ileus, but M. Chomel prefers that of obstruction as more precise, and more indicative of the pathological condition.

The treatment of these cases is represented as very uncertain. M. Chomel places great confidence in ice externally and internally, and narrated ten cases from the "Transactions of the Academy of Copenhagen," which were cured by these means alone. M. Chomel gives the ice in a state of powder, in order that it may reach the stomach without melting, and thus produce the greatest possible amount of refrigeration. He also insists upon copious cold injections thrown up with force, and relates two cases in which he thus relieved the patient after stercoraceous vomiting had occurred. He has no opinion of purgatives, nor metallic mercury, neither of the long tube of O'Beirne.

[The case in question was fatal, and after death a portion of the intestine was found gangrenous, but the *strangulation had disappeared.* The English reader will, probably, think with us, that the case was one of acute enteritis, and that blood-letting, or at least leeching, with mercurialization, would have been effective adjuvants to the ice treatment of M. Chomel.]

2. *Tubercles.*—In a great number of cases of pulmonary tubercle, accompanied by bronchial catarrh, now under his care, Chomel gives indiscriminately eighteen grains of extract of bark, and applies under the axilla an ounce of compound iodine ointment. This is his habitual palliative treatment.

3. *Pessary introduced into the Bladder through a Vesico-vaginal Fistula.*—This case occurred in the practice of M. Jobert, at St. Louis. A woman, aged 45, had a vesico-vaginal fistula, the result of her first labour. She consulted a young surgeon, who declared that she had a prolapsus uteri, and that she must wear a pessary. The pessary was accordingly introduced, and had never since been removed, and the tumour had also disappeared, but at the same time the poor woman, who had continued to pass the urine per vaginam, became the subject of agonizing pain in the region of the bladder and kidneys. The urine became bloody and purulent. On admission she was found as follows:—The walls of the vagina being separated by spatulæ, a fissure was found, of the diameter of half-a-crown; within this a black body was perceived, which was readily reached and turned by the finger: this body was the pessary, which had slipped into the bladder. The os uteri could not be seen by the speculum, being concealed by a large cicatrix, which passed from the rent in the bladder across the vagina. The labia were greatly enlarged and irritated by the urine, as were also the thighs. The pessary was removed through the fistula after great trouble and suffering to the patient. The vesical pains, together with the bloody urine, speedily subsided.

M. Jobert comments upon the unwarrantable carelessness of the practitioner who advised the pessary, and adds a rebuke for the little attention which is often given in an examination per vaginam. He narrates a case in which a surgeon, wishing to insert a pessary, passed it into the rectum by mistake. He noticed as remarkable, the quickness with which all vesical uneasiness disappeared after the removal of the foreign body.

NOTES FROM A PRACTITIONER'S DAY BOOK.*

NECESSITY OF FACILITATING THE DESCENT OF THE DIAPHRAGM IN DISEASES WHICH IMPEDE THE AERATION OF THE BLOOD.

In affections of the chest we should always consider the state of the abdomen with reference to its distension. When the stomach and bowels are overloaded and flatulent, or the peritoneal cavity is filled with fluid, the diaphragm cannot descend, the lungs are prevented from expanding in this direction, and respiration is consequently performed with difficulty. We all experience some degree of shortness of breath after a very hearty meal. A young lady, who suffered from tympanites, always had dyspnœa when the flatulency was extreme. A child, with inflammation of the lungs, was breathing with so much difficulty, that I every moment expected

* (Continued from page 189.)

its death from asphyxia. A warm-purgative, however, carried off a quantity of solid matter and flatus, and enabled the child to live long enough for the disease to be brought under the control of remedies.

DEATH BY ASTHENIA.

A little boy, who had been long labouring under strumous abscesses of the chest and joints, became affected with aphthous ulceration of the mouth and throat towards the close of his lingering illness. He was now so much reduced that I cautioned the friends hourly to expect the fatal termination by syncope; nor was I wrong as to my prognosis of the mode of his death. One morning he had a slight return of the diarrhœa, with which he had been frequently troubled, and on the same evening there was evidently a commencing failure in the cerebral circulation. About two hours before the fatal event, he began to experience an acute pain at the top of his head, accompanied by the loss of hearing, and dimness of vision; the pain induced him to raise his hand to his head, which he began to pat with his fingers. Finding that this proceeding relieved the sensations, he requested his friends to continue the movement, as he was too feeble to do so himself for more than a very few seconds. By this means he seems to have been actually kept alive for nearly two hours. When the patting was discontinued, the pain and the loss of sight and hearing returned, but were again relieved by the movement being resumed; at length this, too, failed. "It will not do any more," he said, "I am going, now," and in a few minutes respiration and circulation had entirely ceased.

NITRATE OF SILVER IN THE TREATMENT OF INFLAMMATION.

A middle-aged country-woman consulted me with deep seated inflammation in the ball of the thumb. The affection had commenced spontaneously, and had existed several days, causing great and constant suffering. She had, hitherto, consulted no medical man, but had attempted to relieve herself by making an opening with a pen-knife. The thumb was exceedingly hard, tense, and tender, and when I pressed it a little matter oozed out through the puncture. Without a moment's hesitation, I made a deep and free incision along the front of the phalanx; though this gave great and immediate ease, it was too late to save the bone, which died, and gradually separating from the soft parts, after the lapse of some weeks, was removed entire with a pair of forceps. She was almost well, when, one morning, as I was examining the thumb, I noticed that the fore-finger of the other hand was bound up. She was almost afraid, she said, to show it, but confessed that she had been suffering as much from this during the last two days as she had done from the other in the first instance. The finger was hard, swollen, and tender, and her worn countenance quite corroborated her account of the pain. With my former experience in this case, I could hardly hesitate about the propriety of an early incision, to which she gave her consent, but I was willing to allow her the chance of escaping from this infliction. I had frequently seen great relief in similar cases from the application of the nitrate of silver. I took a stick of lunar caustic, and wet and rubbed it very freely over the inflamed part, charging her, although she came from a distance, to let me see her on the following day, intending, if necessary, to make my incision then. She, however, neglected my injunction, and I was quite afraid that her courage would fail until irreparable mischief had taken place. About ten days afterwards I found her seated amongst my other patients quite well. The evening after the caustic had been applied the pain abated, and in the morning it had entirely ceased. A superficial vesication had been produced, and she had herself opened it with a pair of scissors.

HEAD SYMPTOMS FROM OVERLOADED BOWELS.

A little boy, about ten years of age, on awaking one morning, complained of intense pain in the head, and soon afterwards he began to vomit, the sickness recurring at short intervals. About ten, he had a fit of an epileptic character, which lasted seven minutes, and within half an hour a second occurred, of the same duration: I saw him in the afternoon for the first time. The child was quite delirious, and did not appear to recognize his mother when she spoke to him. On my asking him where the pain lay, he pointed to different parts of the room. The face was flushed; the eyes red and suffused; the skin hot and dry; the tungue furred, with a red tip and edges; the pulse beat 120 in the minute, and was of a full and sharp character. The vomiting had now ceased, and as the bowels had not acted during the day, I prescribed three grains of calomel, to be followed in two hours by a full dose of castor oil, intending to order a depletion of some kind when these remedies had well operated. At my visit in the evening I found him on the close-stool, having just given passage to an enormous semifluid evacuation, which would have been large even for an adult; the motion was healthy in appearance, and had no unnaturally foul smell. The child was now quite rational, its face calm, its skin cool, and the pulse soft, though still frequent. There was no complaint of pain, except a slight griping in the bowels. During the night two full-sized motions, of a similar character, occurred. In the morning I found him well, and so he continued.

C. ARNECAPLE.

(To be continued.)

ON THE DOCTRINES OF HOMŒOPATHY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Should you consider the following observations worthy of a place in your Journal, you will much oblige me by their insertion in an early number.

Yours obediently,

J. FAIRPLAY, M.D.

Torquay, April 5, 1848.

"The formula of the fundamental principle on which homœopathy is raised *(similia similibus,)* is in contrast with the opposite principle, which serves as the rule of the old school, *contraria contrariis.* Tne idea which these two formulas express is the following:—Homœopathy expects from vital re-action the *active element* of cure; the ancient system opposes *that element* (whether supposed to exist or not,) to vital re-action. It has almost always believed vital strength to be a passive power which was not to be considered; and when it has supposed this vital force, it has shown by its doctrines, that it was necessary to reduce it, in order to overcome disease; thus it has never sought to act upon it, but by opposing it by contrary methods." —*(From the Tuscan Athenæum, No. XII.)*

What the author intends to convey in some of the

foregoing sentences, I confess myself incapable of finding out. The meaning of the first is, however, sufficiently obvious; to it I will therefore direct some observations, and, as I have frequently met with similar assertions, by the advocates of homœopathy, I suppose they really believe in their truth, as well as persuade many of their readers.

To which members, or class, of what the author calls "the old school," his assertion, that "the principle which serves as their rule," (viz., *contraria contrariis*) applies, I am at a loss to know; I have never met with one. The practitioner who would rely exclusively on the application of such a principle as his rule of conduct in the treatment of disease, must indeed have strange ideas of his profession. Those who have had the most experience, will agree with me, that the dogmata of *a* school are of little service to them at the bedside of a patient, whether it be the Hippocratic homœopathic, or any other. That such a doctrine existed even, was, I believe, totally unknown by the majority of the profession, until pointed out in one of the aphorisms of Hippocrates, by the homœopathists, who, in want of a maxim to antagonize their own, (*"similia similibus,"*) and which having discovered, set about to persuade mankind that the medical profession had hitherto adopted *it* as their Polar star of truth, but which being opposed to the grand discovery of Hahnemann, (only to be paralelled, says the author of our text, by the great discovery of Newton,) the world had consequently, before this time, been physicked exactly in the wrong direction.

It is curious to observe with what pertinacity the homœopathists of the present day adhere to this one remaining maxim, and how quietly they have shelved the other grand theories of its immortal discoverer, concerning psora, sycosis, &c.,—theories which, had they been true, would have proved far more valuable and important in their results than *similia similibus*; but I suspect that this also, like its likes, will ere long share their fate, and be consigned to the tomb of all the Capulets.

Some modern homœopathists have indeed thought proper to give an entirely new explanation of the doctrine of *similia similibus curantur;* they say that what are called "symptoms" of a disorder, are signs of the means by which nature sets about its cure, and indicate her method of eliminating from the system any morbific matter by which it may be oppressed; therefore, what can be a more rational treatment than that by which she is imitated, assisted, or anticipated. There is no doubt much truth in this reasoning, and good in the practice in which it results; I beg, however, to observe, that it is by no means new or uncommon amongst the members of the old school. But how very different is this interpetration of the theory from that propounded by its author, and adopted by the great majority of his followers, both in times past and present. Leaving theories, let us now turn to some of their facts.

It is acknowledged by them that the millionth part of a grain is an ordinary dose. It is difficult to imagine how such a minute particle of *any* substance, dissolved in sugar, and placed on the tongue, can produce an influence on the entire system; but when we come to hear of the millionth part of a grain of such inert substances as common charcoal, or the back-bone of a cuttle fish, producing such wonderful effects, we are, indeed, disposed to pause and ask, "Can such things be?"*

That many disorders, both acute and chronic, have been treated by these supposed remedies, that they have been the only medicinal means employed, and that such disorders have got well *after*, can readily be believed; but that *any* of such disorders have got well *in consequence*, or that they have even had the slightest effect on the cure, (physically,) would, I think, puzzle the profoundest homœopathist to prove.

Such facts (the effects, I mean, said to be produced by these infinitessimal particles of matter,) are, indeed, opposed to all our previous knowledge and experience in physiology, chemistry, and the laws of matter. "Never mind," say their advocates, "they *are* facts, and we can bring analogies in support of their reasonableness." It will not be difficult to discover, that even their analogies are false and untenable. For instance, they remind you that an inappreciable quantity of matter will produce the small-pox or lyssa; that the miasmata which cause the most destructive fevers and other diseases are so minute, that they cannot be analysed or even detected; that a stroke of electricity, a matter so subtle that it cannot be made evident to the senses, may produce instant death.

With regard to small-pox and lyssa, both are induced (when by inoculation,) by the introduction of the matter into the circulation: was it merely placed on the surface of the tongue, in each case it would prove, I suspect, perfectly inert. Of the nature of miasmata, which are the cause of fevers, we know little; but granting them to be minute particles of matter, we cannot suppose that they ever produce their effects merely by coming in contact with the tongue, but with extensive surfaces, such as the lungs and skin. No analogy can, I conceive, fairly be maintained between the action of imponderable matter, such as electricity, and that of ponderable substances.

Supposing an homœopathist to admit all this, he has still one vantage ground over his opponents. He might say, "You have not taken the trouble to test practically the things we tell you; we, on the other hand, have both tested them, and proved them, to be FACTS." *Credat Judœus Apella, Non Ego.*

I will endeavour, in conclusion, to trace the cause why so many of our aristocracy and gentry, so many of our clever, estimable, and in other things, sensible and well-judging neighbours, are led away by these strange doctrines, this *amabilis insania;* and I think the task is by no means difficult.

* I must not in justice omit to state, that such substances are not supposed to possess their medicinal virtues until they have undergone certain mysterious processes of trituration or succussion, by which they are said to acquire a marvellous potency.

(To be continued.)

ACTION AGAINST A RAILWAY COMPANY FOR PROFESSIONAL SERVICES PERFORMED.

Cox v. *The Midland Railway Company*.—This was an action brought by Mr, Sands Cox, an eminent surgeon of Birmingham, against the defendants, the Midland Railway Company. The declaration alleged that the defendants were indebted to the plaintiff in the sum of £50 for work, labour, skill, and attendance in the performance of a surgical operation on one Joseph Higgins, at the request of the Company. The defendants pleaded that they were not so indebted. Mr. Whitehurst, Q.C., with whom was Mr. Hayes, stated that on the 9th of February, 1847, a man named Joseph Higgins was about to return by railway from the Whitacre station, on the Midland Counties line, to Coleshill. When he got to the station it snowed very fast, and in a short time a train arrived with only an open truck and a first-class carriage. Higgins, who had a third-class ticket, was about to enter the carriage, when the guard told him he must get into the truck, and whilst in the act of doing so, the train started and he was thrown on the line, and the wheels of the carriages passed over and severely injured his thighs. By the directions of Mr. Bladen, the station-master, Higgins was conveyed to an inn adjoining the station, and Dr. Davies, physician, of Coleshill, was sent for. Dr. Davies and his son attended the man immediately, and found him in a very weak state from the loss of blood. At a late period of the evening, it became evident to the medical attendants (Mr. Barker and also Dr. Bourne having since joined the Messrs. Davies,) that death must inevitably ensue unless amputation was performed, but the unfortunate man was so weak that it was not deemed advisable to pursue this course without consulting some eminent surgeon, and Mr. Sands Cox was sent for between the hours of two and three o'clock in the morning, and performed the operation successfully. An action had since been brought by Higgins against the Midland Railway Company for compensation, and they agreed to give him £150; but it was distinctly alleged to be exclusive of fees for medical attendance, which the defendants agreed to pay. Mr. Cox afterwards visited the man twice, for each of which visits he charged three guineas, and twenty guineas for the amputation. Mr. Whitehurst remarked rather strongly on what he characterized as the shabby, mean, and most ungenerous nature of the Company's procedure in refusing to liquidate this claim. The defendants, for whom Mr. Humfrey and Mr. Macaulay were retained, did not dispute the justice of the charge, but merely pleaded that they were not indebted; that the defendants' servants had no authority to make a contract with the medical men; such a contract should have been under the seal of the Corporation. His Lordship inquired whether the defendants intended to call witnesses; and on receiving an answer in the negative, it was suggested and agreed to that a verdict should be given for the plaintiff for £27. 6s., with leave for the defendants to move to enter a nonsuit, if the Court above should be of opinion that the Judge ought to have directed a nonsuit.

Davies and another v. *The Midland Railway Company*.—This was an action arising out of similar circumstances to the above, in which a verdict was given by consent for £37. 8s. 6d., with leave to move as before. The Learned Judge suggested that, as it was contended for the Company that no servant of theirs had authority to order medical attendance in cases of accident, they ought to make it publicly known.—*Birmingham Paper*.

[We should scarcely have supposed it possible that a public Company of any pretensions to respectability, with ample funds too, at their command, could for one moment hesitate to discharge the just claim of the surgeons for remuneration in a case like the foregoing. The accident was entirely the fault of their own agents; the poor man had the most undoubted right to expect at their hands the very best advice which could be procured for him; a capital operation was requisite; the order for the assistance obtained was given, and very properly so, by the superior and responsible officer of the station where the accident occurred; and yet the Company have the meanness to endeavour to shelter themselves under some bye-law, or implied understanding, of which it would seem that nobody ever heard. If their officer exceeded his instructions, or the fitting exercise of his discretionary powers, surely he is the person to be held responsible—not to Mr. Cox and the other gentlemen whose services were required, but to the Company,—for any orders which he, as their responsible agent, may give; and the attempt under any circumstances to deprive the surgeons of the fair remuneration to which they were entitled is pitiful in the extreme.—Ed.]

DEATH FROM THE ADMISSION OF AIR INTO A VEIN : INQUEST.

On Wednesday, March 29th, an inquest was held at the Red Lion, Barnes, before Mr. W. Carter, coroner for East Surrey, to investigate the circumstances attending the death of William Richards, aged 39, a coal porter.

Sarah Richards stated that the deceased was her husband, and resided with her at Hammersmith. He died on Saturday last at the house of Dr. Willis. He had been for a long time unwell, but for ten weeks past suffering under inflammation of the windpipe. On Saturday morning he left home about half-past eight o'clock. He would not allow witness to accompany him, but she understood he was to have a seton put in his throat. Witness waited outside Dr. Willis's house for her husband, and had been there about an hour and a half, when she went into the house, and saw her husband lying on the floor, and insensible. She was informed that this state was owing to the operation. She had no charge to make against Dr. Willis.

Dr. Willis said—The deceased applied to me for advice a fortnight before the day of his death. He was labouring under inflammation of the upper part of the windpipe. I first treated him by leeching, then by blisters; and lastly, proposed another method of counter-irritation, namely, a seton. This is a method by which I have cured similar cases. Setons have been introduced hundreds of times in the same part for the disease termed goître. Deceased came to me on Saturday morning, about nine o'clock. I set him in a chair. I pinched up the skin with the finger and thumb of the left hand, and immediately thereafter thrust in the seton-needle, armed with a strip of lint. The needle entered two inches and

a-half above the breast bone, and not at all near the jugular vein, or other large blood-vessel. At the moment of its entrance I heard a slight momentary hissing sound. For an instant I fancied I had opened into a subcutaneous abscess communicating with the windpipe; but almost at the same moment, when I looked in the man's face, I saw that another and far more serious event had occurred—that the rushing of the air was not out from the windpipe, but into some small vein which had been necessarily implicated in the operation. The man became pale, fainted, and then became rigid and convulsed. I sent for Mr. Coppleson, the rector, my nearest neighbour; and dispatched a servant to Putney for Dr. Cormack, who was with me in half an hour. He entirely concurred with me as to the nature of the accident. We consulted together, and resolved on blood-letting, as in the circumstances the best thing which could be done. We wished to relieve the right side of the heart. Dr. Cormack bled him. Before the bleeding he was almost pulseless; after it the pulse became good, and he seemed, in every symptom, a little better. Dr. Cormaek was with deceased when he died, at twelve minutes past four. My opinion is that death resulted from the convulsions excited by the entrance of air into a vein divided by me in the trifling operation of the seton. This is a very rare kind of death. It has however occurred several times, and in the hands of Dupuytren and of Sir Astley Cooper.

Professor Syme said—I was sent for to see deceased. Dr. Willis made to me the same statement as to the case which he has now made. I concurred as to the nature of the accident, and approved of what had been done to save the man. Passing a seton in this situation is quite common; and it was a proper measure in this disease. In performing the operation it was impossible to avoid wounding small veins; but no foresight could have anticipated such a result, or any danger. I examined externally the wound of the seton with reference to the situation of the large vessels, and am satisfied that it was so remote from them that they could not by possibility be implicated. In my judgment, there was no want of skill or care on the part of Dr. Willis. He had no control over what took place. I never saw such a case before, but have read of them, and have seen experiments on animals.

Dr. Cormack corroborated Dr. Willis's testimony. He was of opinion that the deceased died from convulsions, produced by the admission of air into the veins. The treatment used to deceased was that sanctioned by recent scientific research. He thought a *post-mortem* examination ought to take place.

The Jury consulted for a few minutes, and then returned the following special verdict:—"Accidental death from the entrance of air into a vein in the neck during an operation performed by Dr. Willis; but the Jury cannot separate without expressing their opinion that such operation was cautiously and skilfully performed; and as it appears by the evidence adduced, the said operation was fully warranted by present practice."

After the inquest the body was examined anatomically. It was found that the large vessels of the neck were uninjured; that the right auricle and pulmonary artery were distended with frothy blood; and that the the lungs were emphysematous.

General Retrospect.

PHYSIOLOGY.

EXPERIMENTS ON ANIMAL HEAT.

Dr. Demarquay has made numerous experiments on animals, with the view of ascertaining the modifications of the animal heat—1st, by pain; 2nd, by loss of blood; 3rd, by the ligature of certain vessels; 4th, by inflammations; 5th, by strangulation of the intestines; 6th, by the administration of various poisons. He arrives at the following conclusions:—

Pain is attended by an increase of temperature: hæmorrhage, when rapidly fatal, produces little or no change in this respect.

The ligature of the abdominal aorta causes, in a few hours, a diminution of temperature, of 8° to 10°, (18° to 22.5° F.;) that of the femoral artery caused, in the thigh, a fall of temperature of only 2°—5° F. As a general result, the ligature of veins caused less diminution of heat than that of arteries.

Every external inflammation is attended by an increase of temperature, both general and local; but the local temperature, in a part far from the centre of the circulation, never equals the internal temperature, *i. e.*, of the rectum. The ligature of the vessels of a part, either before the excitement of an artificial inflammation, or during its presence, does not prevent or modify the increase of temperature in the inflamed part.

Strangulation of an intestine produces a rapid and general fall of temperature. The reduction is greater when a loop of intestine is included in the ligature, than when this is passed circularly round any portion of it. The fall of temperature is also greater in proportion as the ligature is placed near the stomach.

Among poisonous agents — digitalis, belladonna, croton oil, and strychnine, produce a pretty rapid increase of temperature; while the contrary effect is produced by cyanide of potassium, corrosive sublimate, arsenic, tartar emetic, muriate of morphia, and ammonia. The inhalation of æther produces a fall of temperature, which begins with insensibility, and goes on progressively when the inhalation is continued, so as to produce death of the animal.—*Archives Générales de Médecine*, Dec. 1847. *From the Theses of Paris for* 1847.—*Monthly Journal*, April, 1848.

DIFFERENCE BETWEEN THE COMPOSITION OF ARTERIAL AND VENOUS BLOOD.

The results hitherto collected concerning the comparative analysis of arterial and venous blood, are very contradictory. While in the experiments of Prevost, Dumas, and Lecanu, more water was found in venous than in arterial blood, Hering and Franz Simon have found the contrary. Hering found more albumen and fibrin in arterial than in venous blood, in sheep and oxen, but less in the horse. According to Prevost and Lecanu, arterial blood contains more globules than venous; Hering and Simon report the opposite. From recent analyses, made by Poggiale and Marchal, it appears arterial blood contains more water and less solid matter than venous, but the latter

contains less albumen and fibrin, while the globules preponderate in the venous blood.—*Union Médicale*, Janv. 29, 1848.

PRACTICAL MEDICINE.

LARYNGOTOMY IN FEVER.

Dr. Frey, of Manheim, directs attention to the frequent occurrence in fever of lesions, threatening fatal obstruction of the glottis. The principal of these are simple mucous inflammation, fibrinous exudation, and deposit of typhus matter, with its sequelæ, ulceration, &c., in the neighbourhood of the glottis. He observes that the degree of lividity of the surface is a false measure of the amount of danger. He is not deterred from operating where any degree of vital power remains, by the fear of hæmorrhage or subsequent suppuration. *Zeitschrift für Rat. Medizin*, and *Monthly Journal*.

NEW METHOD OF TREATMEFT IN PHTHISIS PULMONALIS.

Reasoning from the well-known efficacy of nitrate of silver in conjunctivitis, and other external inflammations, a Dr. Gastaldi, of Piedmont, has adopted the plan of causing phthisical patients to inhale the powdered substance, by which means it becomes applied to the ulcerating pulmonary tissues. For this purpose he makes a mixture of one part of powdered nitrate of silver, and two parts of powdered charcoal. This mixture he places in an inhaler, and mixing it with the contained air by agitating the vessel, the patient is made to breathe it. No account is given of the results of his experiments.—*Revue de Thérapeutique* Janv. 1848.

SURGERY.

TREATMENT OF BURNS BY ICE.

M. Jobert has recently treated several severe burns by the constant application of bladders of ice. The results of this treatment are stated to be most satisfactory, for not only is the sphacelation (the chief source of the subsequent disfigurement,) greatly limited by the action of cold, but the suppuration is rendered less abundant, and the cicatrices have been thin and destitute of the unsightly bridles, caused by concentric retraction. The ice bags are applied over the burnt surface, and maintained day and night for many weeks, no other dressing, unless simple cerate, being used. The relief to suffering which is thus afforded is stated to be almost complete. When the burn is very extensive, the prolonged cold bath is superadded. Another advantage which is stated to accrue from the practice is the prevention of the secondary visceral inflammations which are so frequently the cause of death in severe burns. Burns of the face and of the trunk have been cured with promptitude, a simplicity which is surprising, and have left but trifling cicatrices.—*Annales de Thérapeutique*, Janv. 1846.

[The editor of the *Annales* remarks upon the apathy of French surgeons, as regards any modification upon their established routine of practice, whence it appears that Mr. Jobert's plan does not find extensive favour among them. We are not aware that it has been much employed in this country, and we have therefore thought it advisable to call the attention of our readers to it, in connection with the valuable information on the same subject, which Mr. Crompton is engaged in collecting.]

MR. SYME'S TREATMENT OF CALLOUS ULCERS OF THE EXTREMITIES.

Dissatisfied with the usual methods employed by surgeons, the author states that in 1829 he advised the application of "a large blister over the sore and neighbouring swelled parts of the limb, which has the effect of speedily dispersing the subcutaneous induration and thickening, so as to relax the integuments, and thus remove the obstacle to healing action. In the course of a short time, seldom exceeding a few days after the blister has been applied, the surface of the ulcer, however deep it may have been, is found to be on a level with that of the surrounding skin, not of course through any process of reproduction or filling up, but merely from the removal of interstitial effusion, allowing the integuments to descend from the position to which they had been elevated, as may be readily ascertained by measuring the circumference of the limb, before and after it has undergone the effect of blistering. But, along with this change of form, the ulcer in other respects no less speedily acquires the characters of a healing sore, assuming a florid colour, affording a moderate discharge of purulent matter, and presenting a granulating surface with surrounding margin of cicatrizing pellicle. No subsequent treatment beyond the attention requisite for ensuring quiet and cleanliness is needed, and recovery is completed, not only more quickly, but with much less tendency to relapse than when accomplished by other means.

"The facility, rapidity, economy, and lasting effect of this treatment, seem to give it a decided advantage over the other methods in use; and, so far as I am aware, no one who has tried the plan ever afterwards hesitated to employ it in preference to any other. In order to derive the full amount of benefit which the practice affords, it must be carried fairly into effect; and with this view, the principle upon which it is founded should be distinctly understood. I still entertain the opinion originally expressed, that the blisters act beneficially by inducing a process of absorption. The enlargement of the limb being of secondary formation, and resulting from the continued irritation of a sore allowed to remain unhealed through neglect or improper treatment, when once established, prevents the contraction of granulating action, by which alone solutions of continuity, not within reach of union by simple adhesion, admit of reparation. Pressure, the horizontal posture, and all other means that tend to remove the obstacle thus presented, will promote the patient's recovery. But of all the means that can be employed for this purpose, blisters appear to be the most efficient, and should therefore be employed for the remedy, not only of the purely indolent and callous ulcer, but of other kinds, which, in addition to their own peculiar characters, show evidence of complication with indurated enlargement of the limb. From this condition it is hardly necessary to mention that the œdematous swelling of weakness

and impeded circulation must be distinguished."—*Contributions to the Pathology and Practice of Surgery.*

NEW AND SIMPLE METHOD OF APPLYING LIGATURES TO POLYPI.

The recommendation of this method is its great simplicity. M. Favrot takes two gum elastic catheters, of convenient size, and cuts off the end of each just below the eye; he then doubles a piece of silk, of necessary length, and inserts the loop into one catheter, the two ends, joined or not, into the other, and brings each extremity out of the lower end of the catheter. This being arranged, the next step is to separate the two threads between the upper extremities of the catheters, and to pull one down in the form of a loop, leaving only one above, which is carried up to the pedicle of the tumour. The application then is as follows:—

The catheters or sounds, together with the interposed thread, are carried up to the base of the tumour, the loop of the thread which has been pulled down being held on each side with the respective catheters. This being done, the said loop is allowed to pass over the tumour, the two catheters being transferred to the same hand; all that is required is then to tighten the thread by drawing its two ends, when as is readily seen, the loop glides out of the other sound, and encircles the pedicle of the tumour.—*Revue Médico-Chirurgicale*, Janv. 1848.

OBSTETRIC MEDICINE.

COMPRESSION OF THE AORTA IN POST-PARTUM HÆMORRHAGE.

[The annexed case is given as a practical illustration of the value of the proceeding advanced by M. Seutin, in the memoir of which we gave a translation in our last number.]

In a case of hæmorrhage after delivery, in which every means had failed to arrest the flow of blood, M. Escalier succeeded in stopping it by compression of the aorta above the umbilicus. He considers this method to be useful, not only by arresting the hæmorrhage, but also by sending the blood back towards the brain, so as to prevent the convulsions which often prove fatal after large losses of blood.—*Union Médicale*, Fevr. 10, and *Month. Journal.*

PRINCIPLES OF MEDICAL LEGISLATION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In answer to your appeal to the members of the Association to furnish the Council with their opinions upon the provisions of the new Charter proposed to be given to the London College of Physicians, and upon the propositions for a general measure of medical legislation, said to have been agreed upon by the heads of the two Colleges, the Apothecaries' Company, and some self-constituted body, styled the National Institute, but which in reality appears to be little more than a second edition of the Apothecaries' Company, I beg to refer the Council of the Association, and you, as Editor of the Journal, to those declarations of principles which have so frequently been made in speeches of the President of the Council;—in resolutions of almost every annual and special meeting of the Association;—in memorials addressed to Secretaries of State;—and in instructions given to the various Committees of our body, appointed specially to watch over the question of Medical Reform, as embodying the only principles that would or could be satisfactory and just to the profession, or of benefit to the public at large, and to ask the Central Council and yourself if the recently proposed measures agree with our deliberate and frequently recorded opinions. If they do, our course is perfectly clear; we must regard them as satisfactory, and accept them with pleasure and gratitude. If they do not accord with our opinions, one course is equally plain and simple; we are bound to reject them without hesitation, and openly and unmistakably express our dissatisfaction at the attempt made to override our recorded wishes. We must do this or stultify ourselves.

So frequently have our principles been declared in the annual reports of the Council, which have been unanimously adopted by the meetings, that not only every member of the Association, but, I may say, nearly every member of the profession, is familiar with them, that it is altogether unnecessary I should point them out in detail. I, however, must, in the present aspect of affairs, and especially after the notices in the Journal, recal your attention to some of them; and lest I should be supposed to speak too strongly, I will quote the very words used. In the memorial presented to the Secretary of State, in 1842, it is stated—

"The principles to which we are desirous of calling your attention, as being those recognized by the Provincial Association, and upon which, as we conceive, any measure intended for the regulation of the medical profession should be founded, *are uniformity of the primary qualification*, to be tested by sufficient examination; *equal right* in every member of the profession to practise throughout her Majesty's dominions; and *the adoption of the representative system* in the formation of the councils or governing bodies.

"In submitting these views, we are assured that we express the wishes not only of the numerous Association with which we are ourselves connected, but also those of a very large number of our professional brethren throughout the country."—*Report of Council at Exeter*, 1842.

The italics are not mine but those of the Report.

At the annual meeting at Leeds in 1843, the report of the Council again states that, hearing s measure was about to be submitted to Parliament, it had been thought right to memorialize Sir James Graham, employing nearly the same words:—

"The Council cannot resist respectfully stating that, in their opinion, no reform can be effectual or permanent, unless it provide for the efficiency and respectability of the whole profession, by securing uniformity of the primary qualification, tested by sufficient examination, equal right to every member to practise throughout her Majesty's dominions, and the adoption of the representative system in the formation of the councils or governing bodies.

"The Council would most earnestly press upon Sir James Graham the necessity that the state of the medical profession in the provinces, as well as in

the metropolis, should undergo a searching investigation before any bill for the regulation of the medical profession, or any part of it, be introduced into Parliament."

And so strong was the feeling of the meeting, that on the proposition of my lamented friend Dr. Williamson, who "thought it highly desirable, in consequence of the powerful act against principles which were at present employed to produce an impression, in some degree hostile to the principles of medical legislation, that a deputation would produce much greater effect than the presentation of a memorial, however ably such a document might be drawn up," a deputation was unanimously appointed to enforce the above opinions.—*Journal*, August 5th, 1843.

Again, at the meeting at Derby, specially called for the purpose of considering the bill introduced into Parliament by Sir James Graham, the following resolution was unanimously passed by the meeting, having been previously prepared and recommended by the Central Council:—

"That further to ensure the object of a sufficient uniform primary qualification for every medical practitioner, without which the equal right to practise every department of the profession ought not to be conceded, it seems desirable that the *diploma of Licentiate of Medicine should be required of all who may hereafter propose to enter the profession, and previous to their being entitled to claim admission to register in any other grade.*"

Again, at the Sheffield meeting in 1845, Sir James Graham having introduced his amended bill, on the recommendation of the Council, a "Committee was appointed to take the subject generally into their consideration, and to report to this meeting before it separates." This report contains the following:—

"They think it necessary also to entreat he will make it imperative upon *all* who may hereafter be admitted to practise in *any* of the recognized branches of the profession, that they shall, in their *common entrance through one portal*, undergo such an examination as shall exhibit a competent knowledge in *all* the departments of medical science. Further, that this examination shall be uniform in every part of the united kingdom, and shall be a legal qualification for practice. *The Committee think that any measure which shall not recognize this uniformity of examination, will be unsatisfactory to the profession, and detrimental to the best interests of the public.*"

Not only was the report unanimously adopted by the Association, but the Secretary was specially instructed to forward it, without loss of time, to Sir James Graham, directing his attention "respectfully but earnestly to the same, as embodying the *only principles* of medical legislation which will be satisfactory to the profession."—*Journal*, August, 6, 1845.

Lastly, at the Norwich meeting, in 1846, Mr. Crosse, the President, was requested, on behalf of the Association, to sign petitions to both Houses of Parliament, in favour of the Registration Bill, just then introduced by Mr. Wakley; and at a subsequent part of the year, a deputation, which at last was permitted to approach the Home Secretary, Sir George Grey, obeyed their instructions, and impressed upon him "the principles adopted by the Association and hitherto acted upon in all their reports and published documents."—*Journal*, August, 1847.

These are then the matured opinions of the Association—not hastily formed, but adopted after long thought and mature deliberation, and solemnly repeated through a long series of years, as affording the *only* basis upon which medical legislation can rest.

What are the principles proposed in the documents now before the profession? Registration upon a plan totally at variance with that petitioned for by the Association, so recently as 1846. Instead of uniformity of education,—one primary legal qualification,—one examination common to all,—and embracing every department of the science of medicine, conferring equal privileges and rights, we find the institution of another examining body with undefined powers and privileges;—no uniformity of education;—none of age for the admission to practice;—no equality of rights;—perpetuating examinations, and consequently qualifications the most various. Instead of securing examinations which shall embrace every department of medicine, it will, as far as law can do so, render the examinations as various and partial, and consequently as imperfect as possible. For the physician will be examined by the College of Physicians, where surgery and midwifery are things not tolerated, and where anatomy has until lately been almost unknown; and the candidate's age must be twenty-six years. The candidate for the Fellowship of the College of Surgeons will be examined by a body, which, by its own recent declaration before a Committee of the House of Commons, is utterly unable and incompetent to examine upon any medical question; and although requiring some lectures upon midwifery to be attended by those who wish to be admitted members, yet considers the knowledge and practical skill, which one would suppose was the object to be attained by the attendance, to be so derogatory, as to unfit its possessor for a seat at its Council Board; and he must be twenty-five years old. The renovated Apothecaries' Company, which will have the advantage of a new name, declares itself (apparently for the purpose of being permitted to struggle into existence,) in future, as it has in times past been determined to be, innocent of anatomical knowledge, and unable to ascertain the surgical competency of a candidate, and those who believe the evidence of the Fellows of the College of Physicians before the Committee of the House of Commons, will be inclined to add the medical also, while arrival at 22 years of age is sufficient to secure presentation at its portals, thus proceeding in a path directly opposite to that which the Association and its Journal have uniformly advocated and proclaimed as the only just and satisfactory one. I therefore feel bound to raise my voice against any measure being passed which shall recognize any such erroneous confusedness, and I call upon the Central Council, and upon you, as Editor of the Journal, not to hesitate about the matter, but to plainly declare the Association will not depart from that which it has so repeatedly declared to be right—*a common examination, embracing all departments of medicine, which shall be the legal qualification for practice; the possession of a certificate of having satisfactorily undergone such examination being required of any person who shall be recognized by the state as a medical man.*

The "principles" bear internal marks of their

parentage: they are the result of corporate intrigues and management, in which the great interest of the profession and public at large is overlooked, for the purpose of maintaining the supremacy of corporate powers. I do not examine these "principles" in detail, objecting as I do, and as the Association has done, to the principle itself.

It may be said, the arrangement it is true is a compromise, but the best that under existing state of things could be done; that "the hostile interests" are too strong to allow that to be carried which all are ready to confess is the only true basis for legislation. But, Sir, I have yet to learn, that a principle admits of compromise. *It may be abandoned, but not compromised,* and abandoned most assuredly it will be, if the scheme be sanctioned by our body. As to the opinion of our inability to carry our plan, I own I do not assent to it, if we are only faithful to ourselves. I have so strong a confidence in the power of truth, that I believe, if not deserted, it will in the end prevail. What great measure even of general legislation has been carried without time and defeat in the first instance? Look at the measures which, during the last ten years, have been passed, and which only a few years before were scoffed at and derided, and had not even the advantage which we have,—an acknowledgement of theoretical truth, but the correctness of many of which is now admitted by their most strenuous opponents. I am no leveller; the Association is no leveller. *Classes in the profession were not made by authority, they were instituted before Halls and Colleges were in existence; they are carried now far more minutely out than any authorities dare or would divide them, and they would still exist though no medical appellations were in being, for not only does the convenience of society require them, but they have a foundation which is immutable in nature itself.*

If the State recognizes the medical profession as a body, let it institute the test which carries the required proof of recognition. The Colleges of Physicians and Surgeons would still exist, and I fully believe would flourish better than now. As few have hitherto rested satisfied with the lowest test and mere legal recognition, so in times to come few, very few, would rest satisfied with it. The physician would go to the College of Physicians, and the surgeon to the College of Surgeons. These would possess their charters, and their fellows be proud of their corporate honors. All would be harmony in the profession, while the state would possess a sufficiency of well, and generally better, qualified practitioners than it does at present, or in my opinion ever will, if the proposed third incorporation be established, which, in the nature of things, *must inevitably be of the lowest grade.*

The uniformity of examination in the first instance is, in my judgment, the only thing required for the greater respectability of the profession, for it would certainly bring with it registration, and whether this be upon one plan or another it matters but little; nor, for one, do I see anything unreasonable in the division into classes. It has convenience to recommend it, nor does it appear why he who has spent more time and undergone a second examination, (as he would do on the plan of a general primary examination,) at a more advanced age, should not, if he wishes it, be placed among his fellows of the same College.

Before I conclude, I would venture to give a word of caution to those of our body, who may have been led into adopting the proposed College of General Practitioners from the tempting promise of "PROTECTION," so prominently put forth in the "Principles." Do not let the bribe lead you astray,—*depend upon it this will never be carried.* It is a mere tub to the whale. The whole course of recent legislation is against increasing the power of inflicting summary fine and punishment. The powers of magistrates are continually being circumscribed. Protection as afforded by law, is more and more growing into disrepute. Besides, were it not, Lords and Ladies, with gentlemen Commoners, are themselves too fond of quackery ever to allow the attempt to be made, even if it were possible, to put it down by fine and imprisonment. No, the most dangerous quackery is that which is within the profession itself, which the most ardent protectionist acknowledges no law can put down. Let there be less within the profession, and depend upon it there will be less without its pale. Save me from them and I have no fear from these. It is they who bring our body into disrepute, and do more harm than all without its limit could effect. Besides, only for a moment think of the undignified position in entering into competition with a mere "quack:" what a confession of want of faith in our noble profession. If it be of such value as it is alleged, and to the full I admit it; if so much time, hard labour, skill, and money, have to be expended in acquiring a knowledge sufficient for its useful practice, surely in the long run it has little to fear from those who are altogether destitute of that hard-earned qualification which the well educated medical man possesses. No, let us rather rely for our protection upon well qualifying ourselves to relieve our suffering fellow-creatures, than upon acts of Parliament and the police court; while the one will certainly not only fail us, but raise a feeling of suspicion and distrust in the public mind against us, the other will secure us its lasting respect and gratitude, and will not confound us with the mere charlatan.

I am, Sir,
Yours faithfully,
THOMAS NUNNELEY, F.R.C.S.E.

Leeds, March 28, 1848.

PRINCIPLES OF MEDICAL LEGISLATION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

You have appealed to the Physicians and to the Members of the College of Surgeons on the subject of the proposed Medical Bill, but you have not addressed a remark to the Licentiates of the Hall. It appears to me that the last-mentioned class is likely to be injuriously affected by the measures suggested.

If I read the *projet de loi* aright, members of the College will be allowed to register both as "Surgeons" and as "General Practitioners," while Licentiates of the Hall will be confined to the list of "General Practitioners." And there is a clause proposed by which persons will be liable to a penalty for assuming a designation which implies that they belong to a class in which they are not registered.

The two propositions above referred to, while they will allow a person with a *surgical* qualification only, to register as if he had a double qualification, thus conferring great privileges in more than one sense on a class who have been hitherto practising *illegally*, will have the effect of imposing degradation and disability on those who have a *medical* qualification only, although the latter are practising *legally*. Thus, we can now style ourselves "surgeons;" we shall henceforth be liable to a penalty for so doing. And again, as respects the double registration, what right has any one to assume that the M.R.C.S. is better qualified to practise *physic*, than the L.S.A. to practise *surgery?*

Like my prototype in Shakspeare, "my poverty, but not my will," compelled me to chose *one* of the two qualifications. I could have qualified as M.R.C.S. a whole year before my curriculum for the Hall was complete; but I preferred the *legal* qualification. I chose what was *then* the substance, rejecting the shadow, though M.R.C.S. sounded better than a qualification derived from a trading company.* I complied with what was *then* the law; why am I *now* to be punished?

Whatever be the new law, let us all start fair, and do not let us, who are only Licentiates, be run into a corner, because we are a despised class, whose very denomination is suggestive of nothing more exalted than "a beggarly account of empty boxes," and because we are in a minority.†

We have *humbled* ourselves by complying with the Apothecaries' Act, let not then the saying be *reversed* which has declared that "he that humbles himself shall be exalted." And in asking this, I by no means wish that the man who, relying on his College diploma only, has proudly refused to apply to the Apothecaries for a "license to practise," should be "abased" because he has "exalted" himself. No, let us *all* start fair.

I am, Sir,

Your most obedient servant,

A LICENTIATE.

* It seems to me that the sensitiveness on this subject is absurd, when we consider that the best and noblest in the land are proud to derive their commissions and what not from the "*Company*" *of Merchants* "*trading*" *to the Indies*.

† We are a minority, but we are numerous. I have had the curiosity to ascertain from the last number of the *Medical Directory*, the qualifications of the first 500 medical officers of Unions, which I find to be as follows:—

M.R.C.S., and L.S.A. - -	308
L.S.A. only - - - - -	66
M.R.C.S. only - - - - -	35

the remainder being composed chiefly of persons possessing the negative medical qualification of having been in practice prior to the Act of 1815, some few of these having, in addition, the positive surgical qualification of the College diploma, while there is a still smaller number whose names I could not identify in the *Directory*.

TESTIMONIAL TO DR. BERNCASTLE.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR

I beg to hand you a list of subscriptions already received on account of the Berncastle Testimonial Fund, for insertion in your next number, and through its pages, to inform the members of the Association that an account has been opened at the London and County Joint Stock Bank, Lombard Street, and that their subscriptions may be paid either directly into the London house, or through any of the branch establishments in the country. Trusting that our members who have in so many instances come forward with resolutions favourable to the conduct of Dr. Berncastle, will not be less ready to express their sympathy in a more substantial shape, nor forget that *bis dat qui citô dat*,

I am, Sir,

Your obedient Servant,

C. WILSON STEEL.

Lewisham, April 12, 1848.

REQUEST FOR INFORMATION ON THE ADMINISTRATION OF CHLOROFORM.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In an "Essay on Anæsthetic Agents" intended shortly for publication, I wish to include reports embracing the following bearings on the subject:—

1. The number of cases in which æther and chloroform have been exhibited. 2. The quantity of each agent respectively which has been inhaled at one time in some particular instances, and in others on an average. 3. The length of time in some particular cases, and in others on an average, during which a state of anæsthesia has been maintained. 4. If possible, the various diseases in which their admissibility has been tested.

This subject is of great professional and national importance, and the report of but one case will swell the aggregate, and receive attention.

Any gentleman thus favouring me will greatly oblige.

I am, Sir, very respectfully yours,

T. CATTELL, M.D.

Braunston, Northamptonshire, April 7, 1848.

Medical Intelligence.

ISOPATHY.

Another species of quackery has made its appearance in Germany, and is now becoming known under the name of Isopathy. We allude to it as one of the passing medical follies of the day. A Dr. Hermann is the Hahnemann or Priessnitz of the new system, which derives its name from the doctrine that the disease of any organ is to be cured medicinally by the use of the analogous organ of some healthy animal. Thus, in diseases of the liver, liver is prescribed; and of the brain, brains; (*calves'* brains we presume;) and the same plan is pursued with the kidneys, spleen, and other viscera.

As it might not be convenient for every individual to eat the substance of the organ, Dr. Hermann professes to make tinctures thereof, and thus to exhibit concentrated essences. Like all new doctrines where imposition on the public is likely to be remunerative, it has made a certain number of converts, who call themselves Isopathists. It is also reported that many radical cures have been effected by this system!—*Medical Gazette*, April 7th.

APPOINTMENT.

James Dixon, Esq., F.R.C.S., has been appointed Assistant-Surgeon at St. Thomas's Hospital, in the room of Mr. B. Travers, junior, resigned.

UNIVERSITY OF LONDON.

Mr. Samuel Cooper has resigned as Professor of Surgery, at University College, London.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, March 31st:—J. Westwood; J. Hebden; J. Baker; C. Walker; E. D. Silver; R. S. Ryan; C. C. Bramwell; W. P. Roberts; F. Pearson; W. R. Raby; N. Bethune.

The following Members of the College having undergone the necessary examinations, were admitted Fellows at the meeting of the Council, on the 12th instant:—Isaac Baker Brown, Oxford Square; Charles Timins, Hon. East India Company's Service, Madras Establishment; William Guest Carpenter, West Street, Finsbury Circus.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, March 23rd, 1848:—Charles Sharp Smith, Fulbreck, Grantham; Thomas Knox Kelly, Liverpool; Christopher Irving, West Burton, Yorkshire.

Thursday, March 31st:—John Mussendine Camplin, Islington; John Farmery Ollard, Wisbeach; William Mutrie Fairbrother, East Dereham, Norfolk.

Thursday, April 6th:—Samuel Tayleur Gwynn, Wem; Thomas Beavan Rake, Shaftesbury; John William Harper, Hitcham, Suffolk; Joseph Lawrence, Bath; Joseph Hinton, Bristol; William Rowland Raby, Birkenhead; Samuel William Aldred, Great Yarmouth; Hartley Samuel Laycock, Liverpool; Thomas Armstrong, Brecon; Wm. Benham, London.

OBITUARY.

Died, March 7th, in Plymouth Grove, aged 74, James Davenport Hulme, M.D., of Ball Haye, in the county of Stafford.

March 12th, at Chester, aged 65, Edward Hogg, M.D., formerly of Henden, Middlesex.

March 29th, in the Edgeware Road, James Briggs, Esq., Member of the Council of the Royal College of Surgeons, and Senior Surgeon of the Lock Hospital.

March 31st, of fever, George Mahon, M.D., Medical Officer of the Eyrecourt Dispensary.

April 6th, at Salisbury, aged 69, Henry Coates, Esq., F.R.C.S., Consulting Surgeon to the Salisbury Infirmary, and a Member of the Council of the Provincial Medical and Surgical Association.

April 8th, aged 84, John Welbank, Esq., M.R.C.S.

Lately, aged 82, M. Pierre Joseph Romain Cazenave, Surgeon-Major of the National Guard, Paris, &c.

Lately, of fever, Edward McGrath, M.D., Assistant-Physician to the Workhouse, Scarriff.

BOOKS RECEIVED.

Principles of Medicine, &c. By Charles J. B. TO CORRESPONDENTS.

Communications have been received from B. B. H.; An Old Member of the Association; Mr. Newnham; J. Fairplay, M.D.; Dr. J. Duncan; Dr. Paxton; Mr. Worthington; Mr. C. W. Steel.

Extra L.M. Lond.—The case is under the consideration of the Council of the Provincial Medical and Surgical Association, and will be represented in the proper quarter.

PROVINCIAL
MEDICAL & SURGICAL JOURNAL.

REMARKS ON THE PRESENT ASPECT OF MEDICINE.*

By W. Newnham, Esq., Farnham.

To those who have watched the progress of medicine for the last few years, and who have noticed the first dawn and gradual development of that revulsion from heroic treatment, to a modified system of expectant medicine, it is impossible not to perceive that the great apostle of the Natural History of Disease is the talented author of the pamphlet entitled "Homœopathy, Allopathy, and Young Physic"; and in a review of the present state of medicine, it would be impossible to avoid tracing the germs of the present transition stage, and noticing in detail the structure of this brochure.

In the perusal of this pamphlet, two things especially fastened upon the memory—first, the course of argument which had been adopted in favour of homœopathy in order to prove that its assumed cures were the restorations of nature, not of art; that they were at *least equal* to the ordinary cures of medicine; and, therefore, that the latter might fairly be presumed to be also the cures of nature, (since things which are equal to the same are equal to one another,) until from further information, and the establishment of a natural history of disease, we might be enabled to say what proportion of recoveries would always take place from her unassisted efforts; and secondly, the reason why the public had been asked to sit in judgment upon these matters,—why the weak points of the profession had been exposed to their unhallowed gaze,—and why they had been invited to contemplate the small degree of reliance which could be placed on their medical guides, or on the influence of their medicines. A few words on each of these points, before proceeding to the main body of the question, and before inviting the profession to envisage and to study what appears to be the chief defects in their mental constitution.

It is cheering to find that our author is not a believer in homœopathy; and yet, with this avowed disbelief in its results, it is difficult to understand the sheltering lenity of expression which is everywhere reserved for the system, or the reason why its assumed effects have been so prominently employed as a foil to set off the poverty of genuine practical medicine,—to show that their results are equal,—and that homœopathy, with all its follies, is at least as good as ordinary medical treatment, and that both are indebted for their success to the unobserved powers of nature. It is impossible to understand this without supposing that the author set out upon his avocation with a fixed determination to expose the weak points of medicine, and conceived that the readiest method of doing so would be by a sort of implied parallel between the effects of homœopathy and allopathy, and by the throes of their respective systems to usher in the birth of his favoured offspring, "Young Physic," he should at once be apprehensive that a result thus originating in predilection, should be given to the world with strong marks of paternity, and bearing upon its early manifestations many of the constitutional predispositions with which it might be pretended to be endowed.

Thus setting off from a wrong starting place, not simply upon an inquiry after truth, but rather to establish the dogma that the good results of medicine were in reality the propitious actings of nature; it is easy to understand how favourable to such an hypothesis would be the establishment of such similar results from the inert medicinal, but stringent regimenal, processes of homœopathy, as from the effects of ordinary medical treatment. How then is this attempted to be established? By speaking favourably of Hahnemann and his doctrine, and of the ingenuity and completeness of his system, as a system, and by an appeal to the results of recorded cases. Now, with regard to the former, whose works are all before me at this moment, no one can doubt that he was a man of considerable mind, and that he has woven together a system of unquestioned *uniformity*. But, nevertheless, it is a system which wants the *unity* of truth, because it originated in prejudice, and is merely the clever development of a prejudice. Thus, for instance, it is stated that the first idea of the principle *similia similibus curantur*, arose in Hahnemann's mind from his taking a considerable quantity of bark when in a state of perfect health, and being afterwards attacked by symptoms resembling ague. Now, what are the real facts of this case? The explanation of *science* and *common sense*, and the testimony of an unprejudiced observer are simply this:—that when perfectly well, he took a large quantity of a nauseous medicine, and either from disgust at the remedy, or from the stomach being disordered by so inappropriate a visitant, he became the subject of constitutional irritation, shivering, and subsequent fever! Nothing can be a more

(* Continued from page 201.)

natural sequence; yet this germinates in his mind the idea that *similia similibus curantur*. It is obvious that no sound reasoning could have developed this idea—for no cure was produced—but on the contrary, morbid action; and therefore the idea must have arisen from the previously known fact that bark was a *remedy* for ague, associated with the accident of its having been followed by constitutional disturbance in himself, when the medicine had been taken into a healthy stomach. Thus originating in the most illogical and unphilosophical manner, the prejudice is created, and subsequent experiments are merely the development of this prejudice, which at once becomes a favourite idea from its novelty and singularity. The rest is easy:—a man of talent soon finds his prejudices confirmed, and dresses up results so as to deceive himself and others with a semblance of truth. Taking up this origin of the doctrine, it will be entitled to no other sympathy than that of any ordinary prejudice.

The extraordinary fact of all, is that our author reasons upon these developments, and allows them all the force of facts, and of "evidence in favour of any other medical doctrine, theoretical or practical." That which constitutes this fact so extraordinary, is that he had so recently denied to the evidence of far greater names than Hahnemann and his disciples, the inferences drawn from a similar appeal to the evidence of facts, and held them as valueless, only as it should seem, because they are more rational,—more consonant with nature and truth,—more scientific,—more unsophisticated, but woven together with less subtilty and prejudice. The fact is one which leads to the inference that the object of the writer is the advocacy of peculiar views, and not the application of the same rigid tests for sifting the character of evidence,—and the same denial of facts,—and the same impugning the character of observers, in all the aberrations of professional intellect; and the absence of this impartiality throws doubt upon all his subsequent reasonings and conclusions. I cannot institute a comparison between the relative claims to attention of homœopathy and allopathy; it would lead me too far from my immediate object, and I must be contented to make a few passing observations upon the pamphlet, and thus developing my views as to what is specially required in the present crisis of our science.

But I may not omit to inquire *why* are the public invited to study this subject? Why are they tempted by alluring newspaper advertisements, and a catch-title, to dive into these hidden things? Why are family secrets, and family defects, and family failings, and family shortcomings and misdoings, exposed to the vulgar gaze? Why are our errors, and infirmities, and weaknesses, allowed to pass the bounds of family kindness, and exposed to the unkindness of that world which is never famed for its sympathy with medical men, so long as it enjoys the blessing of health? And why are the ignorant summoned upon a special jury on a cause in which they possess no means of arriving at a correct judgment? It would be invidious to attempt answering these questions: various solutions of the difficulty present themselves, and it is not improbable that the correct one might be fixed upon without much hazard of going wrong. We shall not attempt the solutions, but we shall infer, and we are well assured we shall carry with us the opinion of the wise and good, that this appeal was a grievous error in judgment—an error which cannot be re-called, and which is so grievous as at once to throw a doubt over the soundness of that judgment to which such a practical error did not at once present itself as an evil most sedulously to be avoided.

If, then, we begin the investigation of our author's observations, with the conviction that they originated in prejudice,—that they have been supported by literary unfairness,—and have been marked by want of judgment, we shall have diligently to guard our own minds from the agency of prejudice against many truths which he may have forcibly enunciated; for he *has* spoken some very good and wholesome truths, though they are so disfigured by the garb with which they have been invested, as to be very difficult of recognition.

As to the fact of homœopathy having had many professors and many disciples, this is not surprising where so much selfish interest has been so largely awakened on both sides. The love of novelty is always attractive, and the vanity of being able to administer globules to oneself, and one's friends, is so enchanting, that we can feel no wonder at the multitude of disciples, and should only be astonished that they have been so comparatively few, especially when the escape from swallowing medicine, and paying for it too, is superadded to the former powerful motives. In addition to all this, the real relief which is occasioned to a patient devoured by *ennui*, in being compelled to adhere to a very strict regimen, is quite enough to account for its numerous followers, and also for the good it has effected in that multitude of miseries which have only been produced by eating and drinking too much, and having too little occupation. Then, with regard to its professors, we doubt not that many of them have honestly imbibed the views of the originator of homœopathy,—and that they have sincerely persuaded themselves into its usefulness,—and have seen evidence in its support,—and have been blind to opposing facts,—and have unconsciously arrived at their conclusions through a multitude of grievous sophistications. But there are other young men, who have had their way to make in the world,—who possessed no very definite or present prospect of success,—and who have seen their easy way clearly into competence, through the royal vista of homœopathy,—who have been only too happy to lay aside the days and nights of toil and research required for ordinary practice,—and to throw off its cares and responsibilities,—and to revel in the luxurious indolence of homœopathic apathy. On either side, whether as physician or patient, there has been no torturing sacrifice to make,—no disagreeables to encounter,—while the beautiful light of hope, without an effort, has irradiated the uncertain gloom of futurity.

In the pamphlet before us, we have a succinct and very learned sketch of the origin of homœopathy, and of the development of its doctrines as arising from the idea first conceived in the mind of Hahnemann, that "similia similibus curantur." It will be remembered

that this idea arose in the first place as a prejudice, produced in a highly imaginative mind; and it is not surprising, that possessed of this clue, in all future investigations, he and his enthusiastic followers should discover analogous results in future experiments on the effect of various medicines upon themselves and others. Such is the constitution of the human mind, that once imbued with a prejudice, to reason against its influence is unavailing; and that all its future agencies in this particular direction will be largely characterized by the *idée mère* in which they originated. Aided therefore by this prejudice,—by brilliant imagination,—and by the enthusiasm attaching to the promulgation of a new doctrine, they investigated the influence of certain medicines, and counting for days and weeks together, all the sensations, real and fancied, of themselves and others, attributed all these sensations to the influence of medicine,—assumed that they arose from the mode of its exhibition,—and pronounced this attribution and these assumptions to be the result of experience!

This, then, is all that can be fairly alleged in favour of homœopathy: its origin is in prejudice,—its development in error; above all other systems it possesses the deep, the indelible plague spot of *post hoc, propter hoc*, and has no other foundation for its conclusions. That it is startling from its novelty,—that it is inviting from its simplicity,—that it is agreeable from the boon it holds out to indolence, and from the facility with which it is practised,—and that it possesses a degree of cohesion in its several parts which invests it with the appearance of solidity, is freely admitted; but that these attributes should confer a title to its favourable reception cannot be admitted; that they should even give the privilege of comparison with rational treatment must be denied; and we must enter a serious protest against all deductions drawn from comparisons so instituted.

It is perfectly true that "vain declamations must cease in the presence of an experience that *cannot err*." But what then is that *experience*? This word is frequently misemployed to express the apparent results of an experiment, but in reality the latter has no claim to be affiliated with the former; it is only the repetition of a *post hoc propter hoc* series, and before it can be possibly dignified with the title of experience, it must be a rational and expected result from rational and adequate means. The experience therefore which Hahnemann claims as the basis of his doctrine, must be shown to be rationally coincident with the expected results from certain adequate remedies, or it is perfectly valueless. In order to be true, it cannot be independent of theoretical explanation; dismiss the latter, and it forms the grossest empiricism. How this reasoning bears upon the question of infinitesimal doses is obvious, but we have no space to enter upon these irrational attenuations; all we wish to shew is, that a doctrine originating in prejudice, unsupported by rational theory, and appealing only to the *post hoc propter hoc* ground of support, is not entitled to be put forward as in its effects, parallel to, and equally successful with, ordinary medical treatment. It is perfectly true that Dr. Forbes disbelieves the results of homœopathy, and considers them to depend upon *nature's agencies*, but he has exhausted much talent, and many pages, upon a development of its doctrines; he has favourably invited the attention of the public to those doctrines, and has invested them with an equal claim to attention as ordinary medicine, because he believes that in both cases the success depends upon nature's agency, and not upon the remedies exhibited. He is then very sceptical as to the efficacy of medicine, and as such he has had many prototypes. Happy indeed is it, that professional scepticism does not invalidate professional truth, and does not detract one atom from the great truths of nature,—viz., that certain remedies possess certain powers to produce certain effects, and that if we do not secure those effects, it is not the fault of the remedy, but of its misapplication.

The homœopathist advises, in acute disease, that the instinctive desires of the patient should be gratified in regard to food, drink, &c. Now, reasoning upon this subject, we should not be disposed to admit that the monitions of the nerves of any given organ, when perverted by acute malady, would be such, as in all probability to induce the sensorium to make choice of proper articles for food and drink. It very generally indeed happens, that this perversion induces a loathing of food, and this is excellent; but the thirst occasioned is frequently intense, and the choice of articles to allay this thirst is, in the great majority of instances, erroneous. Such is the fact. Take for instance a case of gastritis; the thirst is intense; and will the instinctive choice of fluids to allay this thirst, among the poorer classes, fall upon gum water, or barley water, or some such simple beverage?—will it not rather rest with intense desire upon wine, beer, or spirits and water? Let experience decide the question, and it must decide in favour of the fact, that alcoholic fluids will be sought for, and if so, not even an homœopathist would say, in gastritis, gratify the instinctive desire for wine.

Again, we are told, that seven-eighths of all chronic maladies are dependant upon constitutional itch,—that nature cannot possibly cure these maladies,—and that even homœopathy would fail, unless they were treated *anti-psorically*. It would be a waste of words and of time to attempt to show the fallacy of what the common sense of mankind must denounce as untrue, but it is based upon the same ground with all the other doctrines of this heresy,—viz., the *post hoc propter hoc* argument. The chronic malady is assumed to arise from psora,—it gets well under anti-psoric treatment, and therefore the thing is proven.* Of course unprejudiced

* It would seem that absurdity in this direction,—that is, absurdity directed by the *ad rem* object, has not yet reached its culminating point, since a new candidate for public favour, attended by its professors, its converts, its patients, and its cures, has just arisen also in Germany, in the doctrine of *Isopathy*, by which the disease of any organ is to be cured medicinally through the employment of the analogous organ of some healthy animal;—as for *instance*, stomach malady is to be cured by the patient being fed on the stomach of some healthy animal; and should this be extremely disagreeable to the patient, it is proposed by the originator of the doctrine, Dr. Hermann, to make tinctures from the said healthy organ, and thus to exhibit its concentrated essence.

professional men will not receive these dogmas, or attend to them, and all we wish to show is, the injustice of placing such irrational views by the side of rational medicine, and claiming for each the same value; for the value of each must be tested by its curative agency, and in both instances this is stated to be the same, and to consist in the simple efforts of nature.

It cannot fail forcibly to strike the mind of the reflective reader, that Dr. Forbes admits the claim of the doctrines of homœopathy to be founded "on grounds even superior to reason, viz.,—experience and experiment." Now it does astonish us, that our author should dignify blindfold prejudiced experiment, as a source of knowledge superior to reason, and that he should have dissociated the results of *experience from reason*, as if in such cases the one could be obtained without the other,—without reasoning upon the results of experiment, and grounding upon these, rational experience, or theory. To such a centrifugal influence from philosophy do great minds yield, when under the unperceived control of some favourite object,—some mentally cherished hypothesis.

The question of *regimen* presents itself for a few words of discussion. We are fully prepared to admit the importance of regimen generally in the cure of disease; and also that the success of homœopathy is dependent on the strictness of its regimenal rules, and its influence upon the nervous system of the patient. But in what respect does regimen differ from medicinal attention? Is not its object the same? Is it less irksome to the patient? Is it quicker and more certain in its agency? Are its sequences more effectual in the removal of disease and the restoration of health? Is it not notoriously the fact, that disorder is removed more certainly, more speedily, more efficaciously, by a combination of appropriate diet and medicine, rather than by medicine alone, or by regimen alone? If the prescriber be sufficiently skilled to select an appropriate diet, so will he be equally skilled to choose medicines appropriate to the prevailing indications.

We apprehend that in general terms it may be laid down, as essential objects in the treatment of disorder, to relieve and repress inordinate action,—to correct morbid action, and to sustain enfeebled power. We will admit that there are two ways in which these indications may be carried out,—indirectly and slowly by attention to regimen—directly and quickly by combining medicine with dietetic regulations. We *may be* in the infancy of medicine, and undoubtedly we have much of ignorance to deplore; but we do know, that the agency of certain medicines is to produce certain effects—effects upon which we may assuredly calculate, if the medicines have been judiciously prescribed. Equally, however, we are, in the infancy of organic chemistry, and of that knowledge, which would enable us to define with certainty, what alterations in the solids and fluids would inevitably follow the adoption of such a prescribed regimen. Our knowledge of the influence of each being equal, why are we to abjure, the safe, certain, speedy influence of medicine, in favour of the equally safe, less certain, and less speedy influence of diet? Not surely, because medicine has been injudiciously prescribed! This want of judgment would operate against both; grand mistakes have been made,—oppression has been treated for feebleness, and the most inappropriate medicine and diet have been directed; but that mistakes have been made, that injudicious treatment has been adopted, that medicine has been wrongfully administered, that the most improper diet has been enjoined, is no reason why medicine is mischievous and diet useless, though it is a grand reason why further inquiries should be made into the operation of both classes of remedies. In order to be useful, regimen must be essentially medicine; and to assert that regimen is required for the cure of disease, is still further to assert that medicine is also required, because equally safe, and a more speedy and certain remedial agent.

We have left for a special reply, one of the above inquiries, viz., is the regimenal plan less irksome to the patient? As a general rule, we decidedly answer in the negative. There are a few persons who will be cured,—not by their altered diet, but by the attention they are constrained to give to such and such regimenal rules; but these are few, and form exceptions to the general rule, that it is less irksome to patients to take medicine than to be everlastingly thinking about their diet and regimen,—their peculiar breakfast—their baths,—their exercise, &c., &c. The greatest difficulty in practice is to regulate the diet and regimenal attentions of patients, the very things on which they are the most inclined to transgress, and which give them the greatest amount of disgust. Why then are we to abjure the powerful aid of medicine, and substitute for it the feeble influence of diet, which in acute disease might be weeks or even months in effecting an impression upon malady which has run its unheeded course in a few hours or days; and which in chronic malady is inert, and leaves the disease to advance more rapidly than can possibly be overtaken by its slow and measured steps? Regimen and medicine are both useful things; but they should never change places. Medicine possesses the great attribute of altering the conditions of the system,—and regimen is a powerful auxiliary, but should always be held as subsidiary.

We quite agree with Dr. Forbes, that we have no "*unequivocal* evidence to prove that medicine administered homœopathically, and in homœopathic doses, has a *positive* power of curing diseases," but we cannot fail to express our surprise at the wavering state of mind which is exhibited, even by this quotation. There is, it seems, evidence, but it is only not *unequivocal*; there is proof, but it is only not quite *positive*, in favour of this assertion; thus being almost in the same position with theoretical medicine in general, and then passing on to the assertion, that the evidence in favour of homœopathy is precisely the same in character, though, perhaps, not the same in *amount*, as that adduced by the defenders of allopathy. But surely Dr. Forbes must have been aware that evidence of precisely the same character, though not of the same amount, may be adduced in favour of many great remedies,—of charms, and of magnetism, all of which he would repudiate, and consider it as "unwise and unphilosophical," to entertain and enquire

into, though they were "matters immediately and nearly concerning human health, human happiness, and human life." We can but feel astonishment that infant homœopathy should be so gently dealt with, while aged practical medicine is laden with all the errors and infirmities, and ignorance, and thoughtlessness of many of its professors. We do think that it would have been far kinder in Dr. Forbes, had he endeavoured to treat the disorders of his brethren allopathically, and not exposed them to the cruel gaze and scorn of mankind.

Our author appears to rely much upon the reports of certain hospitals with regard to homœopathic treatment. We must confess our want of reliance upon statistical tables at any time; we are well aware that by a little clever tact in this confection, and by arranging one disease under the name of another, and by first taking up a prejudiced opinion, which the tables are to support by their results, statistical tables may be made to speak anything, and therefore must be considered more in the light of an exponent of the opinions of the investigator, than as a sure record of facts, and can only be valued in this scale. And if so, their value will be very small, when we consider the tendency of the human mind to imbibe prejudice, and its love of success, and its strong selfish desire to support its own views, that however much we may feel inclined to allow the principle that every system must be judged by its practical efficiency, we cannot admit the still further conclusion that statistical tables are an exponent of that efficiency. We do not therefore consider them "as substantiating the momentous fact, that all our ordinary curable diseases are cured in a fair proportion under the homœopathic method of treatment." Upon this subject we must ask for a great deal more of evidence upon a point which is perfectly incomprehensible to all our ordinary notices and knowledge of nature's operations, and which, as such, demands an amount of proof far exceeding that of any ordinary fact, and in the *absence* of this extraordinary proof we must assume that all these results have proceeded upon the *post hoc propter hoc* principle, upon which we shall now proceed to make a few remarks.

This principle which appears common to both systems, is, however, the only one in which there seems to be community, and we freely admit that it is a mode of reasoning far too common in our profession, and in the world. At the same time, we are not altogether to disregard even this method of argumentation, for we must recollect that such *may* be the fact; that it is only by the accumulation of *apparent* sequences that we are led to calculate on the return of similar effects from similar causes, and that it is only by finding this expectation generally realized that we acquire what is called experience. We say generally, for there will be always in operation, causes disturbing these expected agencies, and it is our business to ascertain these causes, in order that we may know the sources of failure. The ordinary source of failure exists in the injudicious or erroneous application of the remedy; and he will be the best practitioner who is most accurately acquainted with these disturbing agencies, and who, therefore, best knows how to obviate and avoid them. We quite believe in the folly of employing a novel remedy for some important malady, and because the patient has recovered, loudly proclaiming that he has been saved by the agency of the said remedy. But if this remedy shall have been repeatedly exhibited under similar circumstances, very many times, in different places, and by a great variety of individuals, and identical effects shall have been produced, making all due allowance for the modifications induced by peculiarity of constitution, those modifications being always according to the constitutional expectancy, then we should say that the number of *post hoc* phenomena would enable us to profit by the facts, and with the aid of reason and experience, to pronounce that these are also, so far as we can see, *propter hoc;* and at any rate we are justified in expecting similar results from a like practice. And should we be disappointed in this expectation, we have no right philosophically to infer that our first reasoning was erroneous, but only that there has been some defective link in the chain, which has escaped our observation; and that we have actually prescribed the remedy, under circumstances, not suited for its administration. The error has consisted not in the defective power of the remedy,—not in its want of adaptation to peculiar forms of morbid action, but in our having omitted to weigh well some complication, the influence of which we have estimated too lightly, or it has been altogether concealed from our sight. There are a great variety of phenomena which we are justified in expecting, but for the recurrence of which we have no other reasonable ground for expectancy than that they have always followed similar attendant circumstances; and there can be no just reason why we may not adopt the same methods in medicine, provided that we give a sufficient time for the development of ample experience.

(*To be continued.*)

SHORT NOTES OF THE OPINIONS AND PRACTICE OF THE LATE JOHN PEARSON, ESQ., F.R.S., ON SYPHILITIC DISEASE.*

By W. S. Oke, M.D., Physician to the Royal South Hants Infirmary.

Lues in Children.—Children are often seen affected with syphilis from different causes:—

1st. By the application of the virus to a part devoid of cuticle—an excoriated lip may take it from a diseased nipple.

2dly. From attempts made to have connection with them.

3dly. From the mother being affected with the disease.

When a child is affected with lues, the symptoms are not different to those in adults. It is not uncommon to find chancres and gonorrhœa in young females from the attempts of some brutal men who have entertained the vulgar and absurd notion that connection with virgins gets rid of the disease.

* Continued from page 204.

Clear and decisive instances of the disease being communicated by a sore nipple are extremely rare. When the disease has been communicated by the mother, it always appears as secondary symptoms. Children are rarely if ever born with lues; it generally does not appear till a fortnight or a month after birth, and then in the form of flat copper-coloured spots, but redder than in adults. The eruption is seen about the thighs, arms, between the shoulders, and more particularly where the sebaceous glands are most numerous.

The child has generally a sore-throat, and hoarseness—of so remarkable a kind that it can scarcely be mistaken, after having been once heard. The child has also a particular mode of crying; the lips are swelled, and the eyelids often discharge a large portion of matter; this, however, is not from venereal irritation, but from inflammation.

It is sometimes of the utmost importance to form a just diagnosis with regard to venereal affections in young persons, especially when medical men are called to give their opinion in courts of judication.

When there is ground for supposing brutish violence might have been used, we can derive no certain information from the presence or absence of the hymen. It might have been ruptured, perhaps, accidentally, in some other way; neither are puriform discharge, ardor urinæ, and excoriation, proofs of any injury having been attempted, as they all happen without such cause.

These symptoms are frequently cured by purging, attention to cleanliness, and the application of the vegeto-mineral water (diluted solution of the diacetate of lead;) mercury is not necessary, though it very much assists in such cases.

As the attempts of a sound person very certainly produce all these symptoms, without any contagion, so, on the other hand, the mere contact of a person having lues may communicate the disease, and produce them. In boys, ardor urinæ and puriform discharge may be the result of the penis being constantly handled, from their being stone in the bladder.

But in all these cases it is very important to trace the symptoms to their true source, and in such as are of doubtful character, it is best to give just mercury enough to heal the local symptoms, and run the risk of the secondary.

The possibility of hereditary transmission has been doubted by many able men, and amongst the rest, by Mr. Hunter, who urged that neither the secreted fluids nor the blood was capable of communicating contagion, though secondary symptoms were present. Boerhaave and even earlier writers taught the same doctrines.

The saliva, milk, semen, and urine, considered in themselves are not contagious fluids; but if the organs, which secrete them, become the seat of a venereal ulcer, and if a particle of its matter mixed with such secretions come into contact with an abraded surface infection may be the result. Men who are affected with lues, have begotten healthy children; and infected nurses have suckled children without communicating the disease.

To show that the blood, *per se*, cannot communicate infection, wounds produced in a syphilitic patient, will heal as readily as in any other person, unless they occur in parts where the virus actually exists, as for instance, when a diseased prepuce is removed by excision, although the blood and the natural secretions are not of a venereal character, yet if the organs secreting either of the latter fluids are in a diseased state, the properties of their secretions may be so altered as to become capable of producing infection.

It has been urged that the child becomes affected during its passage through the vagina from sores existing there. It has, however, been known that an infant has been born diseased, when the mother had only gonorrhœa for some time before the birth of her child.

It has also been urged that there is no connection between the blood-vessels of the mother and those of the fœtus; but it is certain that the child is furnished with blood from the mother in some way; and if the blood of the mother were contaminated by the presence of venereal matter absorbed into it, the child no doubt would receive infection.

That infectious diseases may be so communicated there are undoubted instances. Forester mentions a case where the eruption of the small-pox appeared on the internal as well as the external parts of a child at birth. That the small-pox as well as the measles have been communicated in utero is certain; and that lues has been transmitted in the same way, admits of the same proof.

When the mother is diseased, the child is often born dead, and very much atrophied; this may arise, not so much from the venereal poison, as from the ill health of the mother or effects of mercury. Children when born alive of syphilitic mothers, have generally a pale shrivelled appearance, and often die in a few weeks, with apparent marks of the disease upon them; and when they are born apparently healthy, are attacked in a few weeks with sore-throat and other symptoms of the disease, which constantly yield to the use of mercury.

Children affected with lues have appeared to communicate the disease to women who have suckled them. The disease, in many such instances, cannot be traced to any other cause, and yields only to mercury.

That the child is not infected in its passage from the uterus, is proved by the circumstance of many women bringing into the world diseased children many weeks after the local symptoms were apparently cured.

It may be asked why the symptoms should not more frequently occur in children before birth, where the infection has been received so long? To this it

may be answered, that the state of the fœtus in utero is favourable to counteract the effects of the virus. It is constantly immersed in a warm fluid, the blood circulates freely, and the sebaceous glands have scarcely begun their functions. It appears necessary that there should be a deposition of the virus somewhere to produce its local effects; but the state of the fœtus in utero is unfavourable to such deposition. As soon as the vessels are exposed to the air, and the vital and natural functions are properly performed, this deposition takes place and the symptoms appear. That this development takes place from the influence of the air, is proved by the secondary symptoms appearing on the most exposed parts, and by the virus never attacking the viscera.

It is to be suspected that the virus never excites any symptoms till the infant is born, it having been previously floating in the blood-vessels, and no deposition therefore having taken place.

Women, who have been affected with lues, and apparently cured, have frequently given birth to unhealthy children. It sometimes occurs that the first child is very much diseased; the second less so; the third somewhat unhealthy; and perhaps the fourth in every respect a healthy child. But all this time it is not to be supposed that the mother is affected with true syphilitic, but rather with syphiloid disease, gradually wearing itself out.

Treatment of Lues in Children.—If the mother be affected with the venereal disease, and the child sleep with her, and if she give suck to it, it will be only necessary for the mother to use the remedy. When the mother is under the influence of mercury, the child's mouth is often extremely sore; but if the child does not become affected by the mercury, it will be right to give it half a grain of the chloride of mercury, twice a day. If the calomel run off by the bowels, a scruple of the mercurial ointment should be rubbed upon the child's body, nearly every day, for five or six weeks.

It is not desirable to salivate a child severely, as it has sometimes proved fatal; children, however, bear mercury so well, that there is more danger in giving too little than too much.

Anomalous Symptoms of Syphilis.—Ulcer of the Uterus.—This has sometimes occurred when the woman has had no external appearance of syphilis; and infection might occur from this cause, when it is disputed by the female from the want of external proofs of the disease.

The symptoms of primary sore on or near the os uteri are—discharge, pain under pressure, and, by digital examination, the discovery of an ulcer, of a superficial character. The uterus will not be found enlarged, but more indurated or thickened than is natural, with its mouth in some measure dilated. This ulcer is attended with flushing of the face, frequent pulse, and a febrile disturbance of the system, resembling hectic fever; sometimes, however, the ulcer remains several weeks without particularly deranging the system. This kind of ulcer should be treated like the primary sore on any other part of the genital organs, and it should be frequently washed with lime water and calomel.

[The use of the speculum has made us better acquainted with ulcers on the vaginal aspect of the uterus; and they appear to be of far more frequent occurrence than they were discovered to be at the time Mr. Pearson delivered his lectures. I was lately called in to a case of this kind, and by the aid of the above instrument, the ulcer was perceived to be superficial, and the surrounding parts of the mouth of the uterus somewhat swollen—shewing the accuracy of Mr. Pearson's statement made without the assistance of modern invention. This species of ulcer ought not to be placed amongst the anomalous symptoms, but with primary syphilitic sores, supposing, of course, that they were produced by venereal infection.]

Loss of Voice.—It is not unusual for venereal patients to have a total or partial loss of voice, attended with deafness; if, then, there be pain of the larynx, and hoarseness, after repeated attacks of lues, the symptoms are to be referred to such a cause, and treated accordingly.

In such cases there will generally be thickening of the mucous membrane of the epiglottis, or, what is worse, ulceration of the larynx and destruction of the valve.

Thickening or stiffness of the epiglottis, so as to prevent its covering the glottis, is removed by mercury; but if there be ulceration of the larynx and destruction of the epiglottis, accompanied by symptoms resembling croup, and if there be at the same time a bad state of health, a quick pulse, and a wasting of the body, the disease always terminates fatally. There is sometimes a peculiar kind of hoarseness, arising from fungi in the larynx, resembling verrucæ, which cannot be ascertained during life. In venereal ulceration of the larynx, the fumes of cinnabar will be the best local remedy, where they can be borne.

[The late Mr. Vance's method of swabbing out the larynx with a solution of Argenti Nitras, may be useful in incipient cases of this kind, and in the more advanced stages, the iodide of potassium, with mercury, will be found the most effectual treatment.]

Eczema Mercuriale, or Mercurial Rash.—In some persons the skin is remarkably susceptible of mercury, whether used externally or internally.

The period at which the rash appears is various and uncertain; in a child, half a drachm of the mercurial ointment, or a dose of calomel, has produced it, and it is sometimes seen when the course has been almost completed.

The rash is first found about the scrotum and upper

part of the thighs, sometimes also at the bend of the arms; it generally affects the lower more than the upper part of the body; there may, however, be occasionally seen, along with the affection of the lower parts, an erythematous patch on each cheek.

In most instances the rash extends over the whole body, producing frequently a tumefaction of the skin, equal sometimes to that seen in small-pox. The heat of the body is increased, the pulse is quick, and the tongue white, but the sensorium is not usually affected.

This eruption is evidently vesicular, but the vesicles are so small at first, as to require a magnifying lens to discover them. They go on increasing till they acquire the size of a pin's head, when they become puriform, burst, and discharge an acrid and irritating matter, which emits a most offensive odour. In a few days the patient may be excoriated from head to foot, one part discharging an adhesive matter, and another a thin ichorous fluid.

There does not appear to be any fixed limitation of the eruption; as it subsides, the skin acquires a pale brown colour, and is left in a state of roughness.

The first desquamation may be succeeded by a second and third, so that the whole body will appear as if covered by a white powder.

When the eruption is universal, it generally lasts five or six weeks, and will sometimes be followed by the separation of the nails, and the falling off of the greater part of the hair of the body.

Such are the appearances with which the disease will be found to correspond, when its form is regular and severe. In other instances it only appears on the arms and inside of the thighs, and it soon dies and disappears.

(To be continued.)

CASE ILLUSTRATIVE OF THE EFFECTS OF A LOADED STATE OF THE BOWELS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

If you think the following notice of a case which occurred to me some time since worthy a place in your Journal, you are welcome to it. It shows at least, in the first place, what a lucky hit will sometimes do; and secondly, that the public are about as apt to bestow their praises as their censures wrongly, when the performances of medical men are under their consideration.

I am, Sir,

Very faithfully yours,

THOMAS E. AMYOT.

Diss, February 28, 1848.

It was in a summer month that I was called over in a very great hurry to attend an old lady, the widow of a farmer. She appeared about fifty-seven or fifty-eight years of age, was very corpulent, and of a florid complexion. I found her supported by chairs, alternately groaning and screaming, with agonies of pain in her right leg, which, from the groin to the foot was swollen, and dark coloured from the turgid state of the blood-vessels; it was intensely tender to the touch, but not œdematous, neither was there any appearance of erythema or erysipelas. Her pulse was rapid and excited, but perfectly compressible; the tongue was foul, and the bowels, according to her own account, *open, or even rather relaxed.* I confess the real cause of the mischief did not at the time strike me, and after cudgelling my brains during a seven miles' ride home, I resolved on simply trying the effect of a brisk calomel purgative, and a saline and senna draught, determining at the same time to visit my patient early on the following morning, and, if possible, to form a just opinion of the real nature of the case. To my great delight, on my second visit, I found the purgative, which I had looked upon only as *a demurrer*, had done its duty most handsomely, having completely removed the pain and swelling,—and what is more, the cause thereof, in the shape of two or three most copious, dark, lumpy, and very offensive motions. I have no doubt the large intestines had been so distended, as to interrupt the venous circulation, and so to cause the symptoms above detailed.

The case at least taught me never to depend simply on a patient's assertion, when there is any cause to suspect *constipation*, but to examine carefully the evacuations, however regularly they may be passed; and if the fæces be flattened in shape, or *loose and offensive, without the symptoms of debility produced by* TRUE *diarrhœa*, to clear the bowels effectually before adopting any other treatment.

DISLOCATION OF THE HUMERUS REDUCED UNDER THE INFLUENCE OF CHLOROFORM, WITH OBSERVATIONS.

By W. NEWNHAM, Esq., Farnham,

At the present time, when it is peculiarly necessary to form just ideas of the value, and the precise position of chloroform, I think it may not be undesirable to chronicle in the Journal, even the following case, which has no pretensions to rarity, or to remarkable skill, or to any other peculiarity, except as illustrating the value of chloroform in certain cases. I am disposed to think the remedy has been taken up too sanguinely by the profession in general, and I am fearful of its abuse; but I doubt not, that it is a valuable agent, and that it will by and bye find its proper level. I have lately become acquainted with a case of fatal consequences following its exhibition, though I am not at liberty to publish it; but I do think that great caution should be employed; before its use is determined upon; nor can I yet bring myself to the conviction, that it is desirable to employ it in all cases of midwifery, though I would not hesitate to give it, where any obstetrical operation were to be performed. The following is a simple statement of the case referred to:—

I was called in by Mr. Yate, of Godalming, to consult about the management of a dislocated humerus, in an old lady, who had met with this accident sixty-one days previously, but who had not known the nature

of the accident, nor consulted any one about it, till she called in Mr. Yate the day before. The dislocation was into the axilla; the usual means of extension and counter-extension were employed by pulleys. Finding that we did not succeed, and that the pain was becoming intolerable to our patient, we determined on exhibiting chloroform; and shortly after she came under its influence, we succeeded in reducing the shoulder, and she has gone on remarkably well ever since. Previously, she had not slept in consequence of pain accruing from the pressure of the dislocated humerus on the axillary nerves, but with the exception of the first night, she has since slept peacefully, and the old enemy to sleep—pain—is completely removed. I do not say, that we *might* not have reduced the shoulder without the aid of chloroform, but I am satisfied that the reduction was facilitated, while the pain to the patient was spared by its employment.

April 10, 1848.

CLINICAL NOTES FROM PRIVATE PRACTICE.*

By W. H. Ranking, M.D., (Cantab.,) Norwich.

2. *Coma from retained Biliary Secretion: Leeches; Cold Douche to the Head; Active Mercurial Purgative: Cure.*

I was called about eleven at night, three months since, to the son of an innkeeper, aged 13. It appears that he had returned from school a few days previously, and had gone to bed in apparently his usual health, at ten o'clock. About half an hour before I saw him, he roused the house by a most piercing scream, and upon his mother reaching his room, he was discovered sitting up in bed, screaming loudly, and staring with an intense expression of terror into a corner of the room. While in this condition I arrived.

I found him as I have just said, staring with fright, and uttering piercing screams. The countenance was flushed, the eyes glistening, the pulse natural in volume, but a little quickened. He took no notice whatever of any one near him, but continued to stare wildly in one direction, in spite of every attempt to attract his attention. He had vomited once. While I was making enquiries as to the antecedents of this formidable condition, he slowly fell upon the bed, and in a few minutes was in a state of complete insensibility. I immediately sent to the nearest chemist for leeches and calomel, and in the mean time had him raised up, and kept a continuous stream of cold water upon the head, first removing the hair; mustard cataplasms were also applied to the calves of the legs. As soon as they arrived a dozen leeches were applied to the temples; and ten grains of calomel were also put upon the tongue, to be repeated in two hours. I staid with him an hour, and left him with returning consciousness, the leeches having bled freely, and the cold douches being continued at intervals of a few minutes. At ten in the morning he was perfectly collected, the bowels had been freely purged, an immense quantity of dark offensive bile having passed. He required no further treatment.

My first impression on seeing this case was, that it was an instance of the sudden invasion of meningitis, an opinion which might have been countenanced by the boy's age, and by the fact that he had lost two brothers, or a brother and sister, of "water on the brain," and was himself of strumous aspect. But the rapid supervention of complete coma, and the absence of convulsions, at once disabused me of this view of the case, and I had therefore no hesitation in attributing the symptoms to sudden congestion of the brain, induced either by the presence of indigestible matter in the stomach, or by the retention of vitiated secretions elsewhere. The age was against the probability of the congestion being due to disease of the cerebral blood-vessels, as was his aspect against the suspicion of the agency of general plethora. I confess, however, that under the urgency of the symptoms, and the clearness of their indications, I felt inclined to leave the pathology to be determined by the progress of the case. The first object was to relieve the cerebral vessels, which was done effectually by the combined effects of leeching, and the cold douche, the latter especially; the second was to remove the exciting cause, which, as the stomach had been freely evacuated, I judged to be seated in the intestines. This was accomplished by the calomel. Many would have used the lancet freely; and as the result proved, by so doing, would have inflicted a very unnecessary loss of blood,—a loss more easily produced than remedied. The cold douche would, I am convinced, if properly applied, in many cases of threatened apoplexy, puerperal convulsions, &c., completely obviate the necessity of the wholesale blood-letting, too often indulged in in such cases; often, I believe, from the convenience with which the lancet is applied, and the little trouble it involves.

The result of this interesting case will, I think, justify the diagnosis at the head of these remarks,—the proximate cause of the symptoms being cerebral congestion; the remote cause, the retention of the fœtid cystic bile which was dislodged by the calomel.

For some excellent remarks on the production of coma by retained secretions, &c., I would refer the reader to a paper by Mr. Corfe, (*Medical Times*, October 9, 1847, or *Half-yearly Abstract*, Vol. 6, p. 25.

* Continued from page 207.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, MAY 3, 1848.

The French medical journals give a lamentable account of the position and prospects of medical men, under the dislocation of social interests at present existing in Paris. It is in vain that the Feuilletonist of the *Gazette Médicale* attempts to be facetious on the subject; his witticisms are evidently extracted from a spirit more disposed to grieve than to be merry. Miserable as the remuneration of the French

physician would appear, when compared with the more liberal fees received on this side the Channel, even the paltry two francs a visit has already become a matter of history. Human nature is pretty much the same everywhere, and one of its failings seems to be, even in prosperity, to consider the doctor's bill the last that need be paid; it is not therefore to be wondered at, that when the money is scarce the poor doctor gets thrown overboard altogether.

At this moment Paris is all but depopulated, as far at least as a profitable "clientelle" is concerned. The rich man flies that he may preserve the remnant of his wealth, the smaller proprietor that he may escape being called up by the "rappel," as a national guard, half a dozen nights in succession. An awful breach is thus made in the visiting list. But this is not all. Not only do the old patients take their departure, but no new ones arrive. One writer, who confesses to having made a comfortable subsistence out of an "hotel garni," inhabited by the more liberal sons of "perfide Albion," suddenly finds himself with nothing to do; and even the consulting physician is to be seen lounging on the Boulevards, and jumps at an opportunity of once more seeing a veritable fee. Another writer, still more unfortunate, tells an anecdote equally demonstrative of the blessings of the "liberté, egalité, fraternité" system. Thinking it prudent to collect his debts while he could, he requested payment of the modest sum of thirty francs, from a once wealthy patient. This gentleman having no ready money, tendered him a bank bill for 500 francs, in exchange for which the doctor gave him the difference (470 francs,) in silver. When he took the bill to a money changer to be cashed, the latter demanded forty francs discount. As he quaintly observes, one need not wish for a large practice of this kind.

The Feuilleton of the *Union Médicale* bears similar testimony. All the rich among the population, those who are possessed of income, and the aristocracy, have fled the capital: of wealthy foreigners not one remains. Commerce and trade are gone to the dogs. Manufactures, *(industrie,)* arts, letters, are no more. So that the doctor who, in the usual state of affairs, had always difficulty enough in converting the gratitude of his patients into sterling coin, is, under existing circumstances, deprived of all his revenues. And, what is singular, there are no sick; the republic is decidedly a most healthy regime. The more fortunate of our brethren are necessitated to put down horses and carriage, to reduce wages and expenses, and to reform to the utmost their household economy. What then must it be with the more numerous class, whose practice scarcely suffices for the maintenance of a moderate existence,—with those whose visits are more frequent in garrets, *(mansardes,)* than at the palace; at the little shop than in the gilded saloons of the prosperous; to the cottager than in the families of the aristocracy. There are among the medical practitioners of Paris, (and we have, says the writer, painful acquaintance with the fact,) sufferings unheard of, and these sufferings are borne with a courage, resignation, and devotion, of which no other class of society affords an example.

It has ever been the character of the medical profession in this country, that however clamorous it may be for the fancied benefits of internal reformation, it has shewn itself on all occasions the staunch supporter of social virtues in general, and averse to political iniquities in particular. It is a fact of which to be proud, that while members of other professions, even of that which ought to be a sacred calling, do not hesitate to atchieve a temporary notoriety by pandering to the evil passions and misleading the ignorance of their audience, the ranks of the medical profession seldom produce a mob orator. Their interests as well as their conscience, are indissolubly connected with the maintenance of order, and the preservation of the mutual dependencies of society. If it were otherwise, and many could be found mad enough to embark in the republican phantasies which are now upturning the surface of the commonwealth, the experience of our French brethren as to the inevitable results of such precepts upon their receipts would, we conceive, be sufficient to cure them of their folly.

Reviews.

Deafness practically illustrated: being an Exposition of Original Views as to the Causes and Treatment of Diseases of the Ear. By JAMES YEARSLEY, M.R.C.S.E., Surgeon to the Metropolitan Institution for Diseases of the Ear, &c. London. 1847. pp. 181.

In the course of a brief introductory chapter, we are informed that the aim of the author in publishing the work before us is to prove "that in nine-tenths of the

cases which come before the practitioner, deafness will be found to have originated in a morbid affection of the mucous membrane lining the throat, nose, and ear." "The latter," he continues, "is reached through the Eustachian tube, and according as the disease terminates in simple thickening of the mucous membrane, in adhesions, in partial or total loss of the membrana tympani, in disorganization of the whole mucous lining, in loss of the ossicula, or of the inner membranes of the fenestræ, so is deafness more or less intense and confirmed."—p. 6.

In the second chapter we find an outline of the principal diseases of the ear producing deafness. These are divided into:—1st. Diseases of the external ear—the auricle, external auditory passage, and external surface of the membrana tympani. 2nd. Diseases of the middle ear—the cavity of the tympanum, the internal surface of its membrane, the small bones of the ear with their muscles; and occlusion, stricture, or complete obliteration of the Eustachian tubes. 3rd. Diseases of the internal ear—the auditory nerve, and contents of the labyrinth. Figures of instruments for viewing and exploring the passages, and for other operations connected with aural surgery, are also given in this and the following chapters.

The third chapter is devoted to the subject of catheterism of the Eustachian passages, in which a brief history of the operation, and a description of the mode of performing it, are given. Mr. Yearsley is of opinion that "*no persons labouring under deafness, however protracted, should abandon hope of relief, until their ears have been skilfully explored by catheterism of the Eustachian passages.*" p. 66. It is, however, an operation which requires much skill and tact, both in the performance, and in deriving from it those advantages in the diagnosis and treatment of diseases of the middle ear, which its advocates teach us to expect from having recourse to it.

Many of the affections referred to in these chapters are pretty generally left to the professed aurist, and with the comparatively little attention bestowed by surgeons in general on diseases of the ear, it is well, perhaps, that it is so; but there are numerous cases of deafness which must from time to time come under the notice of medical practitioners connected with derangements of the brain and nervous system, of the throat, and of the stomach; and a due acquaintance with the causes, symptoms, and treatment of such cases, is of much importance to every medical man who values his own reputation, or the comfort and welfare of his patients.

The professed aurist, whose attention is apt to be directed mainly to the ear alone, as Mr. Yearsley very justly observes, (p. 77,) but too often leaves these cases out of view; and if the physician or surgeon is not cognizant of the influence exerted on the sense of hearing by various disordered states of the organs referred to, and especially of the mucous membrane of the fauces and upper part of the alimentary passages, cases remediable, or capable of much relief from appropriate treatment, are allowed to pass without notice, until the injured or impaired sense is looked upon as irretrievably gone. The author's observations on these subjects, in the fourth and fifth chapters of the volume, will be read with advantage by practitioners in general, and afford many useful hints to the physician or surgeon for the detection and management of such cases. They will be found, as well as those on the affections of the auditory apparatus, to bear out his assertion, that the mucous membranes are especially to be looked to in the study of aural diseases; and though ultimately other structures may become involved, the primary morbid action, in a vast majority of cases, would seem to originate in some derangement of the mucous lining membrane, either of the ear, or of parts intimately connected with it.

In a chapter devoted to the statistics of deafness, (chapter 7,) the reader will find some particulars of interest.

The following is a summary of 2000 cases collected by the author from his own private case-book, and from the records of the Ear Institution:—

Portraits of Diseases of the Skin. By ERASMUS WILSON, F.R.S. Fasc. I. and II. London. Folio, coloured plates.

The title selected for this work is admirably descriptive, the plates being strictly portraits, and most faithfully characteristic of the affections represented. It is impossible to speak too highly of the manner in which they are executed, or of the artistic skill with which they are delineated. They are drawn and coloured immediately from nature by Mr. William Bagg, and the accompanying letter press consists of a brief notice of the history and progress of the individual cases delineated, together with some general observations on the nature of the affection, the general principles of treatment, and their application to the instances selected for illustration. Each fasciculus contains four plates, and it is, we learn, the intention of Mr. Wilson to continue the work as appropriate subjects present themselves, issuing about two fasciculi in the course of the year. The plates in the first fasciculus are—A, a case of chloasma or liver spot; B and C, favus confertus and dispersus, or crusted or honey-comb ringworm, representing the same patient with the disease at its height, and when the cure is nearly completed; D, an aggravated case of psoriasis palmaris. In the second fasciculus, plates E and F are representations of the right and left sides of the face of a woman affected with lupus exedens serpiginosus, shewing the disease in progress, and the cicatrices left after its disappearance; plate G. is a case of lichen agrius on the back of the hand, and plate H, a case of melanopathia and leucopathia, or black and white discolouration existing simultaneously in different parts of the skin of the same subject. Nothing can exceed the beauty of these delineations of skin disease; the plate of psoriasis palmaris in particular is truly admirable. We most cordially commend the work to general attention, as likely to prove eminently useful to the practitioner, while it is in the highest degree creditable to the author, the artist, and the publisher.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

March 2nd, 1848.

W. H. PARTRIDGE, Esq., in the Chair.

PARTIAL SOFTENING OF THE CEREBELLUM: CLOT IN THE PONS VAROLII: GRANULAR KIDNEYS.

Mr. Bindley exhibited the kidneys in a state of granular degeneration, removed from a young woman, seven months advanced in pregnancy with her first child, who died after convulsions of an epileptic character.

July 5th, 1847. Mrs. H——, aged 26, short and stout, of temperate but inactive habits, pregnant seven months. Since quickening, her health has been excellent, and she has grown fatter. For the last few days her feet and legs have swelled, and yesterday she was unusually drowsy. After some imprudence in diet, she was seized in the night with violent gastric pain, followed by vomiting and severe retching. During this attack, she had a convulsion of an epileptic character, and when I saw her at eleven o'clock, a.m., had had three more fits. I found her in a dull half-conscious state; her speech was indistinct; face flushed; head hot; pulse 96, full, and incompressible; pupils natural. On attempting to make water, another fit came on. Her hands were clenched; her arms and legs were stretched, and forcibly contorted; lips thrust out; brows corrugated; features contorted; eyelids forcibly closed; face at first livid, soon became pale; respiration laborious and stertorous; tongue thrust out of her month, was grasped by the teeth, and severely bitten. The fit lasted two or three minutes. Twenty ounces of blood were taken from the arm, and leeches applied to the temples; the hair was cut off, and spirit lotion applied to the head, and calomel and other purgatives administered. The placental soufle was audible, and there was no show nor sign of labour.

Five, p.m. Had three more fits, and quite unconscious; pulse 96, hard; purgatives rejected by vomiting; no evacuation from bowels or bladder. Calomel and jalap powders were placed upon the tongue, and a purgative enema ordered. The blood drawn has a large loose clot.

Ten, p.m. Convulsions continue; pulse 84, occasionally intermitting, hard, and incompressible; respiration frequent; pupils dilated and sluggish; os uteri firmly closed. Sixteen ounces more blood were taken from the arm, after which the pulse rose, and became small and soft; eyes drawn to the right, with a quivering motion. Eight ounces of urine were drawn by the catheter; it had a deep brown colour, specific gravity, 1.018, acid re-action, and deposited albumen abundantly, both by heat and nitric acid. Croton oil was given by the mouth, and assafœtida and colocynth by injection. The membranes were ruptured by passing a female catheter through the os, and the liquor amnii discharged. The abdomen, which had been tense, became softened. The convulsions continued through the night, coma supervened, and she died at 10 a.m., about thirty hours after the first attack.

Autopsy, twenty hours after death. There was a good deal of subcutaneous fat. *Head:*—Little or no congestion of blood in the sinuses and veins on the surface of the brain, and no serous effusion. The brain itself was paler than natural, and there were two or three tea-spoonfuls of fluid in the ventricles. At the base was a small clot lying upon the upper border of the pons Varolii, between the origins of the third pair of nerves, extending downwards by the side of the basilar artery, and upwards along the under surface of the anterior lobes.. There was also softening, with discoloration, to a small extent, in the left lobe of the cerebellum, and some ecchymosis about its crura and upper surface. *Chest:*—On both sides some old adhesions; on the right they were between the lungs and diaphragm; lungs and heart sound. *Abdomen:*—

Diaphragm adhered generally to the liver by fine cellular bands. The great omentum (which was remarkably free from fat,) was attached by its free border to the brim of the pelvis and abdominal parietes, drawing down some way the transverse colon, between which, and the margin of the liver, were some old cellular bands. With the exception of the kidneys, there was nothing worthy of notice in the other abdominal organs. The uterus contained a healthy looking fœtus, of about the seventh month. There was no fæcal accumulation in the colon. Both kidneys presented similar morbid changes; they were of ordinary size and shape, the right, the larger of the two, and most diseased, rather soft and flabby. On laying them open, the cortical portion was found to have lost its natural appearance, being of a greyish-green colour, of soft texture, and mottled; scarcely any portion of it remained healthy, and the degeneration extended between the cones of the tubular structure, and also to some of these. On stripping off their investing membrane, the external surface was rough and granulated, and of a pale grey colour. The renal arteries and veins appeared natural, but the small portion of aorta removed with the renal arteries presented the ordinary atheromatous condition on the fatty degeneration of Gulliver. The blood was tested for urea by Mr. Charles Palmer, crystals, small in quantity, having the characteristic shape of nitrate of urea, were discovered under the microscope.

GRANULAR KIDNEYS: CLOT IN THE CEREBELLUM.

Mr. Bindley also presented the kidneys in an advanced stage of granular disease, and the cerebellum with a large clot of blood, taken from a man sixty years of age.

Mr. J. E——, aged 60, a plumber and glazier, a broad-shouldered stout man, of low stature, with large head, and short thick neck, constituting what is usually called "the apoplectic make." Has for many years been subject to frequent attacks of gout and gravel; the urinary disorder taking the form of copious deposits of uric acid and urates. He has also passed by the urethra several small uric acid calculi. He took the alkaline carbonates freely, and occasionally colchicum, with saline aperients. The attacks of gout became less frequent, and the urine altered in character. With these exceptions, and an attack of cerebral congestion three years ago, followed by paralysis of the right side, from which he recovered completely in a few days, he had fair health till about eight months ago; he then began to complain of pain, and aching in the loins, drowsiness, palpitation of the heart, and dyspnœa, with cough; headache and vertigo, and occasionally sickness and vomiting. Was dejected and low, and said he thought he should go deranged. The urine was more copious in quantity, and less high in colour; the only note I have of its condition was made in June last; it was then turbid, and in a few hours acquired an ammoniacal odour, of specific gravity 1.018, strongly alkaline, with an abundant whitish deposit, which under the microscope was found to consist of prisms of triple phosphate, and amorphous granules of phosphate of lime, which disappeared on the addition of acetic acid. This urine effervesced with nitric acid. There was increased dulness on percussion over the cardiac region, with a powerful impulse, but no abnormal sound. He continued pretty much in this state till December, when he had an attack of influenza, from which he never fully recovered. Latterly he complained much of severe pain in the left loin, shooting through to the front of the abdomen. There was no anasarca nor œdema. On the morning of the 13th of February last he was seized with apoplexy, and was bled to the extent of twenty-six ounces. Died the same day at noon.

Autopsy, eighteen hours after death.—*Head:*—There was but little blood in the sinuses and in the veins on the surface of the brain, and the cerebral substance was remarkably exsanguine; the arachnoid was opaque, and underneath was a small quantity of turbid serum; there was a little bloody serum in each lateral ventricle. In the left lateral ventricle was found the tapering extremity of a large clot of blood, passing backwards through the third and fourth ventricles, which it distended to the cerebellum, where it had originated: it occupied the anterior portion of the cerebellum, which to a great extent around the clot was softened and broken up, as was also the valve of Vieussens; the arteries at the base of the brain exhibited small atheromatous deposits. *Chest:* Lungs and pleuræ sound; no effusion. The pericardium contained about four ounces of turbid serum, and presented a punctated redness. The heart was covered with fat. The *left* ventricle was enormously hypertrophied, its walls measuring at their thickest part one inch and a quarter, and the fleshy columns with their tendons had undergone the same augmentation in size; the size of its cavity was about natural. One of the aortic valves was thickened and ossified along its attached border, but not so as to interfere with its function. The walls of the right ventricle were thinner than natural; the other cavities and valves sound. The structure of the heart had its healthy red colour. *Abdomen:* Great deposit of fat in the omentum and mesentery, and about the kidneys; the diaphragm and liver were adherent; the liver was rather large and firm, and but little congested; spleen hepatized; the kidneys were of small size, of firm consistence, and of a pale greyish colour: on stripping off their proper tunic, the external surface was rough and scabrous, exhibiting here as well as internally an advanced stage of granular degeneration; on their surface were several small cysts. The morbid changes were most marked in the left kidney, where was a large deposit of fat around its infundibulæ, and two small calculi, of the size of horse-beans. The other organs were healthy. The urine found in the bladder deposited a moderate quantity of albumen, with heat and nitric acid: it was turbid and pale, and its density was 1.013.

The calculi have been examined by Dr. Percy, and found to consist of triple phosphate, around a nucleus of clotted blood.

ACUTE LARYNGITIS; TRACHEOTOMY.

Dr. Fletcher exhibited the trachea after the operation of tracheotomy, in a case of acute laryngitis, in a woman,

aged 48. Dr. Fletcher was summoned late at night, and found the patient suffering from symptoms of so urgent a character that he at once decided that tracheotomy must be performed instantly. Whilst awaiting the arrival of the surgeon the symptoms became so alarming, that he was induced to attempt some temporary relief by freely scarifying the soft palate, tonsils, and back of the pharynx with a lancet; the operation gave instant relief; the swelling of the parts subsided, and tracheotomy was consequently deferred. The following evening, however, the alarming symptoms returned; the face was blue; the nails livid; the patient was delirious and saw visions. Tracheotomy was performed at eight p.m., by Mr. Amphlett. Dr. Fletcher observed, that after the division of the lining membrane of the trachea, dark bloody serum flowed from the mouth and from the incision in large quantity. He had noticed a discharge of a similar fluid from the incision during the operation of tracheotomy on a former occasion, whilst an attempt was being made to enlarge the opening in the trachea, and was consequently led to believe that it probably issued from the submucous cellular tissue of the larynx, which was likely to be in a very œdematous condition. The operation afforded an extraordinary amount of relief, and there appeared every hope that the case might terminate favourably; but on calling on the following morning, he found the patient was dead.

In the *post-mortem*, the larynx only was examined by the gentleman who undertook to perform the dissection, in consequence of an alarm being created by the approach of the friends. Hence the cause of death was not discovered. The larynx itself was not opened until the morbid appearances had somewhat subsided; the mucous membrane was very loose in its attachments, probably from serum having been effused in considerable quantity into the submucous cellular tissue; there was no deposit of lymph. The incision had divided the two first rings of the trachea.

INTUS-SUSCEPTION OF THE CÆCUM AND COLON.

Mr. Blake detailed the case of a child, aged ten months, who suddenly screamed violently, and fell apparently into a fainting fit. Mr. Blake was sent for; he placed the child in a warm bath, and calomel was administered. It was in great pain, had vomited, and had passed two fæcal evacuations, with bloody mucus. There was great pallor of the skin; with a blue tinge. Five hours afterwards it was seen in consultation by Dr. Fletcher, and castor oil injection given. The sickness continued, a large quantity of blood mixed with mucus was passed by stool, with violent straining; warm water injections were employed withot affording relief. The child lived about 48 hours in extreme pain, with constant violent straining. On a *post-mortem* examination a double intus-susception of the large intestine was found; the cæcum, with the inferior portion of the ascending colon, had been drawn into the upper portion of the ascending colon, and this last, with its contents, had become included within the tranverse colon, which retained its usual situation in the abdomen. The invaginated portions were not confined by lymph, but could be drawn out without much difficulty; there was a sparing deposit of lymph on the peritoneal surface of the ascending colon. It is a remarkable fact that the parents had lost another child, at the same age with the subject of the present case, from the same disease. The subject of this case is described as a healthy child, but liable to constipation.

INTUS-SUSCEPTION OF THE LARGE INTESTINES INTO THE RECTUM.

Mr. W. S. Partridge exhibited an intus-susception of all the large intestines.

The subject of the case was a child aged four years. The first symptom was the voiding a large quantity of coagulated blood. The child lived three days; there was no evacuation per anum, except a little mucus tinged with blood; there was vomiting, and shortly before death the matter vomited had a fæcal odour. On a *post-mortem* examination, the whole of the colon with the cæcum had disappeared, having become invaginated into the rectum, carrying with them a portion of the meso-colon, and the lower end of the ileum; the rectum was completely filled by the intestines it contained. The upper portion of the included mass of intestine did not present any appearance of adhesion, but from the firm resistance opposed to any attempt to draw it out, it seemed to be attached to the lower part of the rectum.

DEPOSIT OF EARTHY MATTER IN THE PLACENTA.

Dr. Mackay exhibited a placenta spotted over with earthy matter. The patient was 28 years of age; it was her first child; she had miscarried twice; has been married three years. She had suffered severely from the ordinary sympathetic affections of pregnancy during the first three months, and the last month of gestation; she had also complained of tenderness over the uterus, but of no fixed pain. Formerly she had suffered from dysmenorrhœa. Hæmorrhage occurred for a single day three weeks before her confinement, and returned in considerable amount during the early stage of the labour. An hour after the termination of the labour the hand was introduced into the uterus, and the placenta, which adhered to the uterus, was extracted with some difficulty. The patient did perfectly well. The general structure of the placenta was normal; but there was a rather copious deposit of earthy matter, in spots, scattered over its attached surface.

Foreign Department.

HYDRARTHROSIS OF THE SHOULDER-JOINT, SUCCESSFULLY TREATED BY INJECTION OF IODINE.

By Dr. Jules Roux,

Professor of Anatomy and Physiology at the School of Medicine at Toulouse.

(Translated for the *Provincial Medical and Surgical Journal*, from the Memoirs of the Royal Academy of Medicine Vol. 13. 1848. By Thomas Crosse, Esq.)

The author, at the commencement of his communication to the Society, refers more especially to the effect upon the neighbouring parts of serous collections in enarthrodial joints, the chief of which he states to

be,—considerable elongation of those extra-capsular expansions which the synovial membrane sends to the tendons of the muscle around the joint, (to facilitate their movement,) distension and stretching of the muscles, with impairment of their contracting power and flaccidity after evacuation of the fluid from the joint.

He says—The gradual distension of the muscles covering orbicular joints, prevents their contraction, (at least at certain times,) and causes them to exercise upon the effused fluid an incessant action, of which the result is—dilatation of the unresisting fibrous capsules, and elongation of the extra-capsular serous expansions. It is thus that they form a kind of serous hernia, sometimes of considerable size, round the collection of fluid in a joint. At the shoulder-joint, the extra-capsular expansions which the synovial membrane sends to the tendons of the infra-spinatus, subscapularis, and long head of the biceps, may acquire such dimensions in hydrarthosis, that fluctuation becomes perceptible in the middle part of the arm, axilla, and even in the infra-spinous fossa. At the hip-joint, where the fibrous capsule is so resistant, the fluid, acted upon by the muscles, easily distends the expansion which the lining membrane of the joint sends over the tendon of the psoas and iliacus muscles, and a large pyriform bag is developed in the midst of the muscles of this region, with perceptible fluctuation in parts far removed from the joint.

In some cases also, the author adds, these extra-capsular synovial expansions are themselves the seat of the dropsy, when the communication with the joint becomes obliterated, and large swellings form around it, the origin and true nature of which it may be difficult to recognize.

After reviewing the various remedies which have been employed for the relief of these collections around joints, and referring to the experience of MM. Jobert, Velpeau, Bonnet, Guiselle, and others, respecting the use of setons, and the puncturing with subsequent injection of the cavity, Dr. Roux gives the particulars of the following case, which occurred under his notice, and was successfully treated by the injection of iodine into the joint:—

CASE.

Joseph Fournier, aged 47 years, a labourer, residing in the Quartier of St. Marguerite, near Toulouse, of sanguine temperament, good constitution, and good general health, in the month of June, 1843, was attacked with a quotidian intermittent fever, which remained upon him till the following November. For its relief he had frequent recourse to purgatives. In the September previous, he had experienced a pain in the left wrist, followed by swelling, and loss of power in using the hand. He exposed the affected part to the vapour of hot aromatic water, and after twelve days he was enabled to resume his habitual occupations. In the month following, towards the beginning of October, he was seized with an acute pain in the right hip-joint, increased, on moving the lower extremity, and which, after awhile, left him of its own accord. At the commencement of December, whilst lifting a heavy stone, he was attacked with a very acute pain in the left shoulder-joint, which returned from time to time, in all increased movements of the limb, during the succeeding six months, and became so severe in August, 1844, that he was obliged to discontinue his work. He states that during these eight months the size of the shoulder had insensibly increased in volume, and its movements become more difficult and less extensive; so much so, that for a long time he could only use the forearm of the left side, and could only move the arm with the assistance of the hand of the opposite side. Leeches, poultices, frictions, various ointments, blisters, and aromatic fumigations, were used without benefit.

I saw the patient for the first time on the 1st of August, 1844, eight months after the onset of the disease. On the day preceding he had suffered very severe pain in the affected shoulder, which had subsided, so that he permitted me to examine the parts conveniently, which I found in the following condition:—

The left arm about one-third of an inch longer than the right, hangs by the side of the trunk, inclined a little from within outwards, relatively with the axis of the body. The forearm of the same side, bent almost to a right angle, rests upon the chest; the elbow projecting outwards, is supported by the right hand of the patient; and the body is, upon the whole, somewhat inclined to the left side. The left shoulder is evidently increased, and the seat of a considerable tumefaction, which has effaced all its roundness and *contour*, and extends from above, below the acromion process, to the tendon of the deltoid; and from before backwards, from the axilla to the posterior scapular region in the infra-spinous fossa. The head of the humerus cannot be felt; the skin covering it is tense and shining; fluctuation is manifest throughout the whole extent, but is most evident from the post-scapular to the axillary region, or rather from the external scapular region to the two just quoted, and the hollow of the arm-pit, as far as the border of the great pectoral muscle.

The movements of the afflicted joint are very slight. Extension is impossible; abduction of very little extent; adduction somewhat more decided; rotation very obscure, and no circumduction; the forcible movements of the arm are difficult, of small extent, and painful; pressure exercised on the different points of the swelling is accompanied with a painful sensation to the patient. This examination, and the information given by Fournier, made me diagnose "a dropsy of the shoulder-joint," the cause of which might be rheumatism;—dropsy, which had extended to the extra-capsular prolongations, which the synovial membrane sends to the tendons of the long head of the biceps, the infra-spinatus, and subscapularis muscles. This alone could explain the dimensions of the tumour, its great fluctuation, and the condition of its movements; nevertheless, this was not the opinion of many surgeons, who saw it, but thought it an abscess developed around the joint. The patient was tired of suffering from a disease which had resisted all treatment, and which, nearly depriving him of the use of a limb, hindered him in his occupation. He wished to be cured, and

agreed to submit to any means which it might be thought necessary to adopt. I determined to evacuate the fluid by a subcutaneous incision, and then to use compression. I plunged a trocar into the middle of the infra-spinous fossa, and when (from the want of resistance,) I readily perceived that the instrument had reached a serous cavity, I withdrew the trocar, in proportion as I buried the canula. Adapting a syringe, I drew off 500 grammes (about twenty-four ounces,) of thready viscid synovia, of a deep yellow colour. The tumour became diminished in its whole extent and the fluctuation was replaced by a clammy and flaccid condition of the muscles. One's finger could now distinguish the head of the humerus, which could easily be displaced from the glenoid cavity. After this simple operation (which caused but slight pain,) a patch of gummed taffeta was placed on the little wound, some thick compresses retained by pins were methodically applied, and the arm supported by a sling. The patient returned home on foot.

The first operation was unhappy in its result; the little wound cicatrized by the first intention, but in spite of the pressure that was always exercised on the shoulder, the fluid returned, and the tumour gradually regained its original size. Fifteen days after evacuation, it presented the same characters as it possessed when first seen. I then decided to have recourse to the injection of iodine, and in the presence of MM. Aubert, Levicaine, and others, again operated, making (according to the method of M. Guerin,) a fresh puncture upon the top of the shoulder, near the acromion process, and about three-quarters of an inch from the cellular interval, between the deltoid and great pectoral muscles. I drew off with a syringe 400 grammes (about sixteen ounces and a half,) of a thready albuminous fluid, less yellow in colour than that I obtained upon the first occasion, and possessing all the characters of synovia. The joint still contained a small quantity of fluid, when I injected 300 grammes (about fourteen ounces,) of water, containing 100 grammes (about four ounces and a half,) of the tincture of iodine. When the joint had been distended, I drew off the fluid back into the syringe, in order to pass it again into the joint, and this I repeated three times. I then withdrew the instruments, leaving purposely, as M. Velpeau does, a little of the fluid in the articular cavity. The wound was dressed as before. The following night a severe pain manifested itself in the joint, and the patient had fever, restlessness, and want of sleep. This condition remained about thirty-six hours, but yielded eventually to the application of large linseed-meal poultices.

August 17th, three days afterwards. The little wound is almost healed, and there is only a slight discharge; the swelling of the joint is moderate; there is some œdema; an obscure fluctuation is perceptible at various points, (principally in the infra-spinous fossa, and at the top of the shoulder, so that one would say there was a communication between these two points of the tumour;) he has rather a severe pain over the tendon of the deltoid muscle; sleep and appetite good. The pain became very great during the following days in the infra-spinous fossa, the axilla, and towards the bicipital groove,—three points, corresponding to the three extra-capsular expansions of the synovial membrane of the joint.

On the 23rd the fever was intense, and a phlegmonous inflammation, with heat, redness, and pain, shewed itself in the three points mentioned, without affecting the top of the shoulder. At last, a very circumscribed fluctuation being perceptible, I made three incisions, and evacuated some serum, mixed with a little blood and albuminous flakes, and the patient was relieved. The three wounds were dressed simply with cerate and charpie. There was a slight discharge of serum and pus for some days. The openings became fistulous, and did not heal till the end of September. But, six days afterwards, the same scene occurred; the three points again became the seat of a phlegmonous inflammation, which was in vain combatted by diet, leeches, poultices, and emollient lotions. Fluctuation became rapidly evident, and fever, excitement, and pain, yielded only to an incision made into the three inflamed parts, and the evacuation of a sero-purulent fluid, again mixed with albuminous flakes. The joint itself was always free from the inflammation which attacked the extra-capsular expansions. Charpie was placed in the wounds to favour the discharge. After a few days the top of the shoulder near the acromion process became painful, but the pain was speedily subdued by leeches.

In December, when the three wounds had healed, I applied a small blister to the shoulder, and kept it open for twenty days. From this time recovery was no longer delayed; the motion of the joint became more easy and extensive. In extension the arm raises itself to a right angle with the trunk, when one detects an evident crepitus, produced by the rubbing together of the articular surfaces.

September 1st, 1845. The patient is quite well, and able to resume his agricultural labours.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE, PARIS

The meetings of the past month, (January,) have been for the most part uninteresting, the memoirs presented having been few in number and unimportant.

M. Gerardin read a report on the diseases of cloth-manufacturers; in which the only fact of consequence announced, is, that contrary to the opinion very generally entertained in this country, scrofula is neither frequent among them nor severe.

M. Ferrus reported on a memoir by M. Belhomme, entitled—"Localization of Speech in the anterior lobes of the Brain." In this memoir M. Belhomme has accumulated all the facts within his reach in support of his theory; but he has not adduced any new arguments, and therefore leaves the question where it was, at the close of a former discussion.

M. Mordret read notes of three cases of labour in which chloroform was employed:—The first was, a forceps case; the two others natural labours, but accompanied by unusually severe pain. In all, the agent was eminently successful.

M. Vidal (de Cassis,) read a lecture "On the propriety of performing operations at separate intervals,"—that is to say, instead of completing the operation at one sitting, to postpone its completion to the second or third. The operations which he more particularly advises to be thus performed are lithotomy, extraction of foreign bodies from the joints, evacuation of abscesses, &c. We need say no more on this truly French project.

The last meeting was entirely occupied by the nomination of officers, &c.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DES SCIENCES, PARIS.

COMPOSITION OF THE BLOOD.

Several memoirs were presented to this Academy on the chemical composition of the blood;—among them, one by M. Mellon "On the normal presence of copper and lead in the blood." The author maintains in contradiction to Orfila, Flandin, &c., that the blood does contain a definite portion of both metals, as well as of silver and manganese. The lead and copper are not diffused through the fluid, but are found in conjunction with the iron of the globules, and according to him, are in all probability quite as necessary to the vitality of the blood.

FUNCTIONS OF THE SPLEEN AND VENA PORTA.

M. Beclard read an essay "On the Functions of the Spleen and Vena Porta," which is based upon researches and analyses of the blood of the splenic vein and vena porta, relative to the proportions of globules, fibrin, albumen, and water. He has ascertained—1st, that blood taken from the splenic vein always contains fewer globules than the blood of the general nervous system; 2nd, that it contains more albumen and fibrin. The spleen, therefore, so far from being the organ in which the globules are constructed, in reality destroys them. From experiments with portal blood, Beclard has ascertained—1st, that during the first stage of digestion, the quantity of albumen is considerably augmented; 2nd, that towards the close of the process the globules are also increased. The author also concludes that the globules are formed out of the albumen in the vena porta.

MM. Poggiale and Marchal (de Calvi,) likewise contributed a memoir on the constitution of the arterial and venous blood in a case of encephalitis following erysipelas of the head.

COMPARATIVE EFFECTS OF ÆTHER AND CHLOROFORM.

M. Sedillot is the author of a very important memoir on the "Comparative Anæsthetic Properties of Æther and Chloroform." While he admits the advantage of the latter in some respects, the author mentions one of its properties, which has been particularly noticed in this country,—viz., its tendency to accumulation. The effects of æther abate as soon as its inhalation is suspended, but that is not the case with chloroform; on the contrary, the anæsthetic effects seem in some cases to increase; the pallor and coldness of the surface may augment to an alarming degree. For this reason he advises that its inhalation should not be carried beyond the second degree of insensibility, which is evidenced by muscular relaxation. He further states that persons of weak fibre, or who are enfeebled by privation or excess, are readily affected by chloroform, but that the *contrary* is observed in robust persons. To dissipate the effects of chloroform, when carried to an injurious extent, he recommends the inhalation of ammonia, with cold affusions, and, if necessary, artificial respiration. Upon the whole M. Sedillot prefers æther to chloroform.

M. Plouviez narrated experiments on animals, proving that even when apparently dead from the effects of æther or chloroform, they may be restored by artificial respiration.

M. Lallemand reported on four additional cases of *vesico-vaginal fistula, treated by "autoplastie par glissement,"* under M. Jobert.

PROPOSED CHARTER OF THE ROYAL COLLEGE OF PHYSICIANS OF ENGLAND.

We are authorized to announce that a reply to the Memorial presented by the Council of the Provincial Medical and Surgical Association, to the President and Fellows of the Royal College of Physicians, in reference to Clauses 4 and 5 of the proposed new Charter to the College, has been received; and that permission has been granted for the publication of this document. We here reprint the Memorial, in order that the answer of the College may be more readily compared with the suggestions contained in the Memorial.

I. MEMORIAL OF THE COUNCIL OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

To the President and Fellows of the Royal College of Physicians.

The Council of the Provincial Medical and Surgical Association having taken into consideration the clauses 4 and 5 of the proposed Charter of the Royal College of Physicians of England, as printed in the Report of the Select Committee of the House of Commons, bearing date the sixteenth day of July, 1847, and also the objections which have been severally made to the above clauses by graduates of British Universities, and others, practising as Physicians in this country, beg leave respectfully to offer the following suggestions to the President and Fellows of the Royal College of Physicians in reference to these clauses.

1. That a diploma conferring the degree of Doctor in Medicine from any British University, and bearing date prior to the first day of January, 1848, should be received as sufficient qualification, without further examination, for admission to the Royal College of Physicians of England, as an Associate or Member under the new Charter.

2. That the candidates should be required to be of the age of twenty-six years or upwards, at the time of admission, instead of thirty years, as stated in clause 5 of the proposed Charter.

3. That the amount of the entrance fee should be fixed at ten guineas instead of twenty-five guineas.

4. That considering that the Extra-Licentiates of the College had duly complied with the regulations of the College Charter, at the time of their receiving the license of the College to practise as physicians *extra urbem*, and their right to do so being now recognized by law, it would be unjust to deprive them of such right by any retrospective measure, and that therefore such of those gentlemen admitted Extra-Licentiates prior to the first day of January, 1848, as shall be practising as physicians only, at the time of the granting of the new Charter, should be admitted Associates or Members of the College, without further examination.

5. That in all cases of admission to the new order of Associates, or Members, whether of the existing Licentiates of the College, the Graduates of British Universities practising as physicians in the country, or the Extra-Licentiates, testimonials of moral character and general professional conduct should be required.

6. That gentlemen possessing the degree of Doctor in Medicine from any British University, bearing date prior to the first day of January, 1848, but now in general practice, may be hereafter entitled, on retiring from such practice, and being of the age of —— years, to present themselves for admission as Associates or Members of the College; and that such gentlemen, on producing sufficient testimonials of character and professional qualification, shall be admitted Associates or Members without further examination, on payment of an entrance fee of —— guineas, exclusive of stamp duty.

7. The Council of the Provincial Medical and Surgical Association would further recommend to the consideration of the Royal College of Physicians, the propriety of introducing some clause providing for the reception into the College of such gentlemen now practising as physicians, as may have taken the degree of Doctor in Medicine in Foreign Universities of reputation, after having undergone a sufficient course of study, and submitted to regular examination therein.

8. That the Fellows of the Royal Colleges of Physicians of Edinburgh and Dublin, who may be practising as physicians in England at the time of the granting of the new Charter, be also entitled to become Associates or Members of the Royal College of Physicians of England, under the same provisions as those regulating the admission of Graduates of British Universities.

CHARLES HASTINGS, M.D.,
President of the Council of the Association.

ROBERT J. N. STREETEN, M.D.,
Secretary to the Association.

April 11, 1848.

II. Reply of the President and Fellows of the Royal College of Physicians.

The President and Fellows of the Royal College of Physicians return their thanks to the Council of the Provincial Medical and Surgical Association, for the suggestions which the Council has offered to them respecting certain Clauses of the new Charter proposed for the College of Physicians.

It may be satisfactory to the Council to know, as it has been satisfactory to the College to perceive, that the greater and more important part of those suggestions had been already anticipated by a Committee of the College, which Committee, on considering the same subjects, had arrived at the same conclusions as the Council has arrived at, respecting the principal points at issue in those Clauses.

Accordingly, the College, fully entering into the spirit of the first suggestion of the Council, has agreed that the date, prior to which the diplomas from British Universities, to be received as a sufficient qualification, must have been obtained, shall stand, in the 5th Clause, as, "three months previous to the date of the letters patent conferring the New Charter."

The College has also agreed to alter the age requisite in those whom it is proposed to admit as members under the provisions of the 5th Clause from thirty to twenty-six years.

The entrance fee has been fixed at Fifteen Guineas, it being necessary that the members to be entered should contribute thus much towards defraying the expenses attendant upon obtaining an Act of Parliament and a new Charter. And it should be considered that they will obtain advantages the same as, or even greater than, those for which a larger sum has been paid hitherto by all who have been admitted members of the College.

The arrangement recommended in the fourth suggestion respecting the Extra-Licentiates, is precisely that which the College had determined to adopt. And, in accordance with the fifth suggestion, it has always appeared to the College proper to require testimonials of moral character and general professional conduct from all whom it admits as members.

With respect to the sixth suggestion, the College has come to the conclusion that the act of grace for admission into the College, without examination, under the provisions of the 5th Clause, cannot, with propriety, be extended beyond the period of one year from the granting of the Charter.

In accordance with the seventh suggestion, the College has determined that those persons who are practising as Physicians, in England or Wales, with degrees obtained at Foreign Universities, after regular examination, and after residence in a University during not less than two years, shall be admissible on the terms assigned in the 5th Clause. And the College has further adopted the recommendation contained in the eighth suggestion, and agreed that the Fellows of the Royal Colleges of Physicians of Edinburgh and Dublin, now practising as Physicians, in England or Wales, not having degrees from British or Foreign Universities, but who have resided during at least two years in a University, and who have been regularly examined

before their admission as Fellows of those Colleges, shall be admissible as Members of the College of Physicians of England on the terms of the 5th Clause.

It is further to be remembered, that if there should still be any respectable persons, practising as Physicians in England or Wales, who should not be included in any of the classes above-described of persons admissible, under a new Charter, into the College of Physicians of England, such cases may be provided for, as respects registration, by the Clause, for the registry of special cases, contained in the principles which have been proposed for a Bill for the regulation of the Medical Profession.

FRANCIS HAWKINS, Registrar.

College of Physicians, April 18, 1848.

III. Draft of the Charter to the Royal College of Physicians.

From the Report of the Parliamentary Committee of July 16th, 1847.

[We have been also requested to publish the entire Charter as proposed to the Parliamentary Committee of the last session, but it will be borne in mind that the dates will be altered, and that its clauses generally, as well as those to which the preceding documents refer, are open to such changes as circumstances may render desirable.]

Victoria, by the grace of God of the United Kingdom of Great Britain and Ireland, Queen, Defender of the Faith: To all to whom these presents shall come, greeting: Whereas the commonalty or fellowship of the Royal College of Physicians in London have, by their petition, humbly represented unto Us, that the said college was incorporated by letters patent, bearing date the 23rd day of September, in the 10th year of the reign of King Henry the Eighth; which letters patent were confirmed by an Act passed in the session of Parliament holden in the 14th and 15th years of the reign of King Henry the Eighth, intituled, "The Privileges and Authority of Physicians in London;" and that by such Act of Parliament, certain other powers and privileges were granted to the said commonalty: and whereas the said college has also represented unto Us, that since the making of the said letters patent divers other charters have been granted to the said college: and whereas the said college has also represented unto Us, that by an Act of Parliament made and passed in the present year of our reign, intituled, "An Act making provision for the granting a New Charter to the College of Physicians," after reciting as or to the effect hereinbefore stated, and that it was expedient that certain changes should be made in the constitution of the said college, and particularly that new regulations should be made for the election of the officers of the said college, and that the present number of the fellows of the said college should be increased; it was enacted, that it should be lawful for the said corporation to surrender all the charters which had heretofore been granted to them, other than and except the said charter of King Henry the Eighth; and also so much and such part of the last-mentioned charter as should be in anywise inconsistent with, or repugnant to, any new charter to be granted to them by Us; and that it should be lawful for Us to grant, and for the said corporation to accept from Us, a new charter, which charter might make such alterations as should be deemed by Us expedient in the constitution of the said corporation, and might, if We should so think proper, change the name of the said corporation. And further, that when and so soon as the said corporation, under their then present common seal, should have accepted any new charter so to be granted as aforesaid, the acceptance thereof should operate as a surrender of all the other charters of the said corporation, except the said charter of King Henry the Eighth, and should also operate as a surrender of the said charter of King Henry the Eighth, and as a repeal of the first-mentioned Act of Parliament, so far as the same should be inconsistent with, or repugnant to, such new charter. And further, that from and after such acceptance of such new charter, the said charter of Henry the Eighth should stand, and be ratified and confirmed, except so far as the same should be so surrendered as aforesaid; provided always, that nothing therein contained should extend to authorize Us to create any new restriction in the practice of physic, or to grant to the said corporation any new powers or privileges contrary to the common law of the land; and that no such new charter, whether the name of the corporation should be changed or not, should in any wise prejudice, affect, or annul any of the existing statutes or by-laws of the said corporation, further than should be necessary for giving full and complete effect to the alterations which should be intended to be effected by such new charter in the constitution of the said corporation. Now know ye, that We, taking the premises into our Royal consideration, of our especial grace, certain knowledge, and mere motion, have granted, declared, ordained, and appointed, and by these presents, for Us, Our Heirs and Successors, do grant, declare, ordain, and appoint, in manner following; to wit:

1. That the said corporation shall henceforth be styled, "The Royal College of Physicians in England."

2. That the said corporation shall consist of fellows and associates, including a president and council, four vice-presidents, four censors, a treasurer, and a registrar.

3. That all the present licentiates of the said corporation shall be associates of the said corporation.

4. That each of the present extra-licentiates of the said corporation shall be admitted an associate of the said corporation, on the production to the said censors of the said corporation, of testimonials of character and professional qualification which shall be satisfactory to the said censors, and on passing such examination before the said censors as shall be required by, and shall be satisfactory to, the said censors, and on his paying to the said corporation a fee of £25, exclusive of the stamp duty.

5. That every person now practising as a physician in England or Wales, and who shall have taken the degree of doctor in medicine at any university in the United Kingdom of Great Britain and Ireland, after regular examination, (previously to the 1st day of

January, 1842,) and who shall have attained the age of thirty years, and who shall not be engaged in the practice of pharmacy, shall, at any time within twelve calendar months from the acceptance of these our letters patent by the said corporation, in the manner mentioned in the Act of Parliament hereinbefore stated to have been passed in the present year of our reign, be admitted an associate of the said corporation, without any examination, on the production to the censors of the said corporation of his diploma, and of such testimonials of character and professional qualifications as shall be satisfactory to such censors; and on his proving himself to be of the said age, and on his assuring such censors that he is not engaged in pharmacy, and on his paying to the said corporation a fee of £25, exclusive of the stamp duty.

6. That any person who, after regular examination, shall have taken a degree in medicine at any university in the United Kingdom of Great Britain and Ireland, or from any foreign university, to be from time to time recognized by the said corporation, and who shall have attained the age of twenty-six years, and shall not be engaged in the practice of pharmacy, and shall have gone through such course of studies, and who shall have passed such examination before the censors of the said corporation, touching his knowledge of medical and general science and literature, and complied with such other regulations as are or shall be required by the by-laws of the said corporation, shall be intitled to become an associate of the said corporation without being subject to any other election.

7. That there shall be 200 fellows of the said corporation, and that such number shall be hereafter regulated in such manner as hereinafter stated.

8. That the present fellows of the said corporation shall continue to be fellows of the said corporation, and that previously to the 25th day of June, 1845, a meeting, or several meetings of the fellows and associates of the said corporation shall be holden, at which so many fellows as will make up the number of fellows to 200 shall be elected, and that such fellows shall be elected out of the lists of associates who are hereby admitted or shall hereafter be admitted associates of the said corporation, all of whom shall be eligible to be fellows; and that, on the 25th day of June, 1847, and on the same day in every subsequent year, (except when the same shall fall on a Sunday, and then on the 26th day of June,) a meeting shall be holden of the fellows and associates of the said corporation, for filling up vacancies which shall have occurred in the fellowship since the last election of fellows, so as to make up the number of fellows to 200; and that if on the day of holding any such meeting as last aforesaid, the number of fellows and associates of the said corporation shall exceed the number of fellows and associates on the 5th day of June, 1846, then and in every such case so many additional fellows shall be elected at such meeting as will make up the entire number of fellows to a number bearing the same proportion to the number of fellows and associates for the time being, as the said number of 200 fellows shall have borne to the existing number of fellows and associates on the 12th day of June, 1846, or as near thereto as circumstances will permit, the new fellows being always elected out of the list of associates for the time being of the said corporation; but no new fellow shall be elected so long as the entire number of fellows shall bear a larger proportion to the number of fellows and assoociates for the time being than the said number of 200 fellows shall have borne to the existing number of fellows and associates on the 25th day of June, 1846.

9. That the fellows and associates shall have an equal right of voting in the election of fellows; and the fellows to be elected shall be elected by ballot, either by lists or otherwise, as the said corporation shall from time to time determine by their by-laws.

10. That if it shall at any time hereafter appear that any present or future fellow or associate of the said corporation shall have obtained admission to the said corporation by any fraud, false statement, or imposition, or that he shall have violated any by-law, rule, or regulation of the said corporation, then and in every such case, and after such previous notice to and such hearing of such associate or fellow as under the circumstances the president and censors of the said corporation shall think proper, it shall be lawful for a majority of the fellows present at a meeting of the fellows to declare such fellow or associate to be expelled from the said corporation; and thereupon every such associate or fellow shall cease to be an associate, or an associate and fellow of the said corporation, as the case may be, accordingly; and all the privileges granted to such associate, or associate and fellow, as the case may be, shall cease and be extinguished.

11. That the present president of the corporation shall continue to be president of the said corporation until a new president shall be actually appointed in his place; and that upon the day next after Palm Sunday, in the year 1844, and on the same day in every subsequent year, a new president of the said corporation shall be elected, at a meeting of the fellows of the said corporation; but the retiring president shall always be capable of being re-elected; and every president shall remain in office until the actual election of the new president.

12. That at the meeting of the fellows held for the election of the new president, the council of the said corporation shall, out of the first fifty fellows in the list of fellows of the said corporation, nominate some one of such fifty fellows to be proposed to the fellows of the said corporation, to be by them elected president; but if the fellow so nominated shall not be elected president by a majority of the fellows present at such meeting, another fellow shall in like manner be nominated by the council, out of the first fifty fellows in the list of fellows to be proposed as aforesaid, and so on, until a president shall have been elected. The election of president shall be taken by ballot; and in case of any difference in the council, concerning their selection of a president, the president nominated by the majority shall be proposed to the fellows; and in case of an equality of votes in the council, the senior fellow so nominated shall be so proposed.

13. That in case of the death or resignation of the president for the time being, a new president shall with all convenient speed be elected in his place, such election to be made in all respects in the same manner as is provided by the last preceding regulation.

14. That at any time before or at the meeting of the fellows of the said corporation, after the meeting of the fellows at which the president of the said corporation shall have been elected, the president so elected

shall appoint four fellows out of the first fifty on the list of fellows, which four fellows shall be called vice-presidents, any one of whom may act as president in the temporary absence of the president, upon such president expressing his desire to such effect to any such vice-president, in writing, or to the registrar: and in case of the death of the president, the first vice-president for the time being in the list of vice-presidents shall act as president until a president shall have been appointed; and the present president of the said corporation shall, at the meeting of the fellows of the said corporation next after the granting of these our letters patent, appoint four vice-presidents for the purposes aforesaid.

15. That the vice-presidents shall cease to be vice-presidents when a new president shall have been appointed in the place of the president by whom they were nominated.

16. That there shall be sixteen fellows on the council of the said corporation.

17. That the present council of the said corporation shall continue to be the council of the said corporation until a new council have been actually elected in their place; and that on the 22nd day of December next, four fellows shall be elected to make up the number of the council to sixteen; and that on the 22nd day of December, 1844, and on the same day in every year, (except when the same shall fall on a Sunday, and then on the 23rd day of December,) four of the council shall go out of office, and four fellows shall be elected of the council; but the fellows going out of office shall not be re-eligible until they have been one year out of office; and the fellows to be elected as aforesaid shall remain in office until others shall have been actually elected in their place, and that on the same day, other fellows shall be elected to the council, to fill up vacancies occasioned by death or resignation since the last election,

18. That the council shall be elected by the fellows out of their own body by ballot, either by list or otherwise, as the said corporation shall from time to time determine by the by-laws.

19. That in addition to the sixteen fellows so elected, the president, censors, and treasurer of the said corporation shall, *ex-officio*, be of the council of the said corporation.

20. That the present censors of the corporation shall continue to be the censors thereof until new censors shall have been actually elected in their place; and that on the day after Palm Sunday, in the year 1844, and on the same day in every subsequent year, four new censors shall be elected; and censors going out of office shall be re-eligible; and the censors to be elected as aforesaid shall remain in office until other censors shall actually have been elected in their place.

21. That on the day for electing censors, the council shall nominate four of the fellows of the said corporation to be proposed to the fellows, to be by them elected censors; but if any fellow or fellows so nominated shall not be elected a censor or censors by a majority of the fellows present at the meeting, another fellow or fellows shall be nominated at such meeting by the council, to be proposed by the fellows, and so on, until four censors shall have been elected. The election of censors shall be taken by ballot. In case of a difference in the council concerning the nomination of censors, the censors nominated by the majority shall be proposed to the fellows; and in case of an equality of votes in the council, the president shall have a casting vote.

22. That in case of the death or resignation of either of the censors for the time being, a new censor shall, with all convenient speed, be elected in his place, such election to be made in the same manuer as is provided by the last regulation.

23. That the present treasurer of the corporation shall continue to be treasurer of the said corporation until a new treasurer shall be actually elected in his place; and that on the day after Palm Sunday, in the year 1844, and on the same day in every subsequent year, the president shall nominate one of the fellows, to be elected by the fellows as treasurer, in the same manner in all respects as is before appointed for the election of censors by the fellows; and the treasurer shall be re-eligible. And every treasurer shall remain in office until a new treasurer shall be actually elected in his place.

24. That in the case of the death or resignation of the treasurer for the time being, a new treasurer shall, with all convenient speed, be elected in his place, such election to be made in all respects in the same manner as is provided by the last preceding regulation.

25. That the present registrar of the said corporation shall continue to be registrar of the said corporation, until a new registrar shall be actually elected in his place; and that on the day after Palm Sunday, in the year 1844, and on the same day in every subsequent year, the president shall nominate one of the fellows to be elected by the fellows as registrar, in the same manner, in all respects, as is before appointed for the election of censors by the fellows, and the registrar shall be re-eligible; and every registrar shall remain in office until a new registrar shall be actually elected in his place.

26. That in the case of the death or resignation of the registrar for the time being, a new registrar shall with all convenient speed be elected in his place, such election to be made, in all respects, in the same manner as is provided by the last preceding regulation.

27. That the president, council, censors, treasurer, and registrar, shall be considered as remaining in office during the whole of the day on which their successors shall be elected.

28. That the said corporation may, from time to time, by a by-law, change the day hereby appointed for any election to take place; and if, from any cause whatsoever, any election shall not take place on the day hereby, or by any by-law, appointed for that purpose, the same shall take place on some other day appointed for that purpose by the said corporation.

29. That proxies shall not be allowed at any election.

And we do hereby, for Us, and our heirs and successors, further grant, that the duties, powers, and privileges of, and incident to, the said respective offices, shall, except so far as the same are varied by these presents, and subject to any variations therein which may be made by the said corporation, continue to be the same as the duties, powers, and privileges of the same offices respectively now are.

And we do hereby, for Us and our heirs and successors, further grant, that it shall be lawful for the said corporation to admit as an associate of the said

corporation any person who shall have exceeded the age of forty years, on the production to the censors of the said corporation of such testimonials of professional education as shall be satisfactory to such censors, and on passing the usual examination before the censors; and such person shall, after such his admission as an associate of the said corporation, be entitled to have and use the degree or designation of doctor of medicine.

And we do hereby, for Us, and our heirs and successors, further give and grant unto the said corporation, full and lawful power and authority to hold, possess, and enjoy, for the use and benefit of the said corporation, all manors, messuages, lands, tenements, rents, services, possessions, or hereditaments whatsoever, (whether the same are or shall be holden of Us, our heirs and successors, or of any other person or persons whatsoever,) already given, granted, sold, aliened, assigned, disposed of, devised, or bequeathed unto or to the use of or in trust for the said corporation, and to have, hold, take, purchase, receive, possess, and enjoy, for the use of the said corporation, any other manors, messuages, lands, tenements, rents, services, possessions, or hereditaments whatsoever, (whether the same are or shall be held of Us, our heirs and successors, or of any other person or persons whomsoever,) so as that such manors, messuages, lands, tenements, rents, services, possessions, or hereditaments hereinafter to be had, holden, taken, purchased, received, possessed, or enjoyed by the said corporation, shall not at any one time exceed in value the clear yearly value of £2000 above all reprises, according to the value thereof, when respectively acquired by the said corporation.

And we do hereby, for Us and our heirs and successors, further give and grant unto every subject or subjects whatsoever of Us, our heirs and successors, whether incorporated or not incorporated, special licence, power, faculty, and authority to give, grant, sell, alien, assign, dispose of, devise, or bequeath, unto the said corporation, for the use and benefit of the said corporation, any manors, messuages, lands, tenements, rents, services, possessions, or hereditaments whatsoever, (whether the same are or shall be holden of Us, our heirs and successors, or of any other person or persons whatsoever,) so as that the same do not at any one time exceed in the whole the clear yearly value of £2000 above all reprises, according to the value thereof respectively, when acquired by the said corporation.

And we do hereby, for Us and our heirs and successors, further grant, that all the said provisions in the said Act of Parliament of our present reign, shall be, and the same are, hereby expressly confirmed in such and the same manner, to all intents, constructions, and purposes, as the same might have been by being herein repeated; but this present provision shall not be deemed in any way to weaken, control, or affect the provisions of the same Act of Parliament, or any of them.

And we do hereby, for Us, our heirs and successors, further grant unto the said corporation and their successors, that these our letters patent, or the enrolment or exemplification thereof, shall be, in and by all things, good, firm, valid, sufficient, and effectual in the law, according to the true intent and meaning thereof, notwithstanding the not fully or duly reciting the said letters patent, or the date thereof, or any other omission, imperfection, defect, matter, cause, or thing whatsoever to the contrary thereof in anywise notwithstanding. In witness whereof we have caused these our letters to be made patent. Witness Ourself, at our Palace at Westminster, this ——— day of ———, in the ——— year of our reign.

General Retrospect.

ANATOMY.

ON THE STRUCTURE AND DEVELOPMENT OF THE LIVER.

By C. H. Jones, M.B., Cantab.

The author traces the organization of the liver in the various classes of animals. Thus in the Bryozoon, a polype, it is of the follicular type; in the asterias, the function of the liver is shared between the closed appendage of the stomach and the terminal cœca of the large ramifying prolongations of the digestive sac contained in the several rays. Among the annulosa, the earthworm presents an arrangement of the elements of the hepatic organ, corresponding in simplicity with the general configuration of the body, a single layer of large biliary cells being applied as a kind of coating over the greater part of the intestinal canal. In another member of the same class, the leech, in which the digestive cavity is much less simple, and presents a number of sacculi on each side, these elements have a very different disposition; and the secreting cells, although some remain isolated, for the most part coalesce to form tubes, having a succession of dilatations and constrictions, and finally uniting and opening into the intestine. In insects the usual arrangement is that of long curved filamentary tubes, which wind about the intestine; these, in the meat-fly, are sacculated throughout the greater part of their course, till they arrive quite close to the pylorus, where they open; near their origin they appear to consist of separate vesicles, which become gradually fixed together, but occasionally they are seen quite separate. The basement membrane of the tubes is strongly marked, and incloses a large quantity of granular matter, of a yellowish tinge, with secreting cells; another portion of the liver consists of separate cells, lying in a granular blastema, which cells, in a later stage of development, are seen to be included in vesicles or short tubes of homogeneous membrane, often coalescing and exhibiting a more or less manifestly plexiform arrangement. The author has termed this the *parenchymatous portion* of the liver, on account of its general appearance and mode of development, though he has not been able to determine whether the tubes always originate from it. Among the arachnida, the follicular type of arrangement prevails; and the same is the case with the crustacea, the follicles in these last being distinctly visible to the naked eye. In mollusca also we find the follicular arrangement universally to obtain; yet in certain cases the limiting membrane of the follicles cannot be shewn to exist, and the author therefore thinks that its importance is probably not great, but that it serves chiefly to fulfil the mechanical function which its synonym *basement* indicates. The quantity of

retained secretion in the liver of mollusca seems clearly to imply that the bile in them is not an excrementitious fluid; it is used slowly on account of the imperfect character of the respiration.

In passing from the invertebrata of the vertebrate division of the animal kingdom, and beginning with the class of fishes, a great change is immediately manifest in the form and character of the biliary organ; it is now a gland of solid texture, to which the term *parenchymal* is justly applied. Two portions may be distinguished in it,—namely, the secreting parenchyma, consisting of delicate cells, or very often of nuclei, granules and elaborated matters in great part, and the excreting ducts, which, though completely obscured by the surrounding bulky parenchyma, may yet be satisfactorily demonstrated, and traced often to their terminal extremities in the following manner:—If a branch of the hepatic duct be taken up in the forceps, it may be dissected out without much difficulty from the surrounding substance, which is very soft and yields readily to gentle manipulation. When a trunk is in this way removed and placed under the microscope, a multitude of minute ramifications are seen adhering to it; among these, not a few may be discovered, which do not appear to have suffered injury; some are occasionally seen terminating by distinctly closed extremities. More usually the duct becomes very minute, and gradually loses all definite structure; appearing at last like a mere tract of granular matter. In either case there is no communication by continuity with the surrounding parenchyma. Large yellow corpuscles, peculiar cells, and a considerable quantity of free oily matter usually existing in the liver of various fishes, seem generally to indicate a great superiority in the amount of secretory over that of excretory action, and to betoken clearly the feeble intensity of the aerating function.

In reptiles, there is the same arrangement of liver, namely, a secreting parenchyma of cells and an apparatus of excretory ducts, which have the same essential characters as those of fishes; but there exists very frequently in the parenchyma remarkably dark corpuscles, which appear to be masses of retained biliary matter, the import of which, in the situation they occupy, is doubtless the same as that of the similar masses existing in fishes.

In birds, the parenchyma of the liver is remarkably free from oily or retained biliary matters; it often consists almost wholly of free nuclei and granular matter, with scarcely a single perfect cell. The excretory ducts often greatly resemble those of reptiles, sometimes rather those of mammalia; the essential character is, however, always the same, namely, that they terminate without forming any important connection with the parenchyma.

In mammalia, the parenchyma of the liver consists usually of perfect cells, which are arranged often in linear series of considerable length, radiating from the axis of each lobule; these unite at various points with each other, so as to present a more or less plexiform appearance. Each lobule, as described by M. Kiernan, is separated from the adjacent ones by the terminal twigs of the portal vein, and to a greater or less extent by a fissure, though in most animals the lobules are continuous with each other both above and below the fissure. The elaboration of the secreted product seems to be most completely effected in the cells adjoining the margin of the lobules, which are often seen to contain a larger quantity of biliary matter than those in the interior, and to be apparently in the act of discharging it into the fissure; the margin of the lobule then presents an irregular surface with large globules of the secretion clustering together all over it. The capsule of Glisson surrounding the vessels in the portal canals, gives a fibrous investment to those surfaces of the lobules which are towards the canal; but when it has arrived in the fissures, it forms a continuous membrane lining the surface of opposite lobules. This membrane is often truly homogeneous, and closely resembles the basement tissue; there appears occasionally to be a delicate epithelium on its surface, but this, as well as the membrane itself, is often absent when the margin of the lobules is in the condition which has just been described, and which may be termed *active*. The minute branches of the hepatic duct, as they approach their termination, undergo a remarkable alteration in their structure; they lose their fibrous coat, which blends itself with the membranous expansions of the capsule of Glisson; their basement membrane becomes gradually indistinct, and at last ceases to exist, and the epithelial particles no longer retain their individuality, but appear to be reduced to mere nuclei, set very closely together in a faintly-granular basis substance. The mode of their termination is not uniformly the same; frequently they present distinctly closed rounded extremities, between one and two thousandths of an inch in diameter; at other times they seem to cease gradually in the midst of the fibrous tissue, the nuclei alone being disposed for some little way in such a manner as to convey the idea of a continuation of a duct.

These ducts can seldom be discerned in the fissures, but they have several times been seen in the spaces where several fissures unite; they do not form anything like a plexus between the lobules. From the anatomical relation of the ducts to the parenchyma, and from the circumstance that a distinct vessel conveying a different kind of blood is distributed to the hepatic duct, as soon as the liver assumes the parenchymal form, it seems probable that the mode in which the secreted bile is conveyed out of the organ, is by permeating the coats of the minute ducts, in obedience to an endosmotic attraction which takes place between the bile, in which the ducts may be said to be bathed, and a denser (perhaps mucous,) fluid formed in their interior. The large quantity of oily matter frequently existing in a free state in the secreting parenchyma of the liver, which must be regarded as a product of secreting action, seems to suggest the idea that a certain quantity of the biliary secretion may be directly absorbed into the blood, and in this manner conveyed away from the organ, just as occurs in the thyroid body, supra-renal capsules, and other glands unprovided with afferent ducts.

With respect to the development of the liver, the author considers the opinion of Reischert to be decidedly the correct one,—namely, that its formation commences by a cellular growth from the germinal membrane, independently of any protrusion of the intestinal canal. On the morning of the fifth day, the œsophagus and stomach are clearly discernible, the liver lying between the heart, which is in front, and the stomach, which is behind; it is manifestly a parenchymal mass, and its border is quite distinct and separate from the digestive canal. At this period the vitelline duct is wide; it does not open into the abdominal cavity, but its canal is continued into an interior and posterior division, which are tubes of homogeneous membrane, filled like the duct, with opaque oily contents; the anterior one runs forwards, and forms behind the liver a terminal expanded cavity, from which there passes one offset, which, gradually dilating, opens into the stomach; a second, which runs in a direction upwards and backwards, and forms apparently a cœcal prolongation, and a third and fourth, which are of smaller size, arise from the anterior part of the cavity, and run to the liver, though they cannot be seen to ramify in its substance. At a somewhat later period, these offsets waste away, excepting the one which is continued in the stomach, and then the mass of the liver is completely free and unconnected with any part of the intestine. As the vitelline duct contracts, the anterior and posterior prolongations of it become fairly continuous, and form a loop of intestine, the posterior division being evidently destined to form the cloaca and lower part of the canal. The final development of the hepatic duct takes place about the ninth day, by a growth proceeding from the liver ltself, and consisting of exactly similar material. This growth extends towards the lower part of the loop of the duodenum, which is now distinct, and appears to blend with the coats of the intestine. Around it, at its lower part, the structure of the pancreas is seen to be in process of formation. The further progress of the development of the hepatic duct, will (the author thinks,) require to be carefully examined, but the details he has given in this paper have satisfied him of the correctness of the statement, that the structure of the liver is essentially parenchymal.—*Proceedings of the RoyalSociety*, 1847. —*British and Foreign Medico-Chirurgical Review*, April.

NEW MUSCLE OF THE LARYNX.

M. Crouzel has discovered a new internal laryngeal muscle, which he calls the *crico-thyroideus posterior*. This muscle is not constantly present, but it is often so, and offers some considerations of interest to physiologists. It must not be confounded with the external portion of the *crico-thyroideus anterior*. The description by the discoverer is as follows:—

The new muscle is situated above and outside the corresponding crico-arytenoideus posterior; it extends from the posterior aspect of the cricoid cartilage to the inferior border of the thyroid, near its smaller cornu. Its posterior surface is covered by the pharyngeal mucous membrane; the anterior surface is applied to the above-mentioned cartilages. The inferior extremity is inserted into the posterior face of the cricoid cartilage; the superior and external into the lesser cornu of the thyroid. Its action is to draw the thyroid downwards and backwards.—*Archives Générales*, Fevr., 1848

SURGERY.

SIMPLE METHOD OF EXTRACTING A FISH-HOOK FROM THE ŒSOPHAGUS.

Two children amused themselves by playing at angling, the younger taking the part of the fish. After several endeavours to catch the hook in his mouth, the poor child succeeded too well, and determining, it appeared, to play his part to perfection, swallowed the hook. The consequence was, that his brother drew the line, and fixed it at once in the œsophagus. All attempts to extract it proved futile, till the surgeon took a pistol bullet, and having pierced it, put it on the line, and allowed it to slip down to the impacted hook. The weight removed the latter, the point of which sticking into the lead, it was safely returned.—*Revue Medico-Chirurgicale*, Janv., 1848.

NEW SHIELD FOR SORE NIPPLES.

Mr. Lucas, of Louth, makes the following statement:—In the treatment of sore nipples I have found great advantage from the use of a very simple shield. It is made of tissue or silver paper, three and a half or four inches square, rubbed over on one side with some unctuous substance. This is placed over the nipple, and readily adheres to the breast; the few folds are then flattened, and laid in any direction so as to avoid the sorest parts.

I generally use the fat of the deer or calf, which in this part of the country is called "trundle." The fat should be well rubbed in with the finger; it is not necessary that the paper should be more than thinly coated over.

After the infant has been suckled, a fresh paper is usually required; but the cheapness of the application, and the rapidity with which the papers can be made by the attendant nurse, remove any obstacle this might seem to present to their adoption. The paper not only protects the nipple from being rubbed by the linen or clothes, but is so light as scarcely to be felt; it adheres sufficiently to be retained without any kind of support, is easily applied, and costs a mere trifle.

It is occasionally desirable to medicate the papers: in many cases, the use of Arnica montana (in the proportion of ten minims of the tincture to the ounce of fat,) has been attended with the best results.—*Lancet*, April 14, 1848.

POOR-LAW MEDICAL COMMITTEE.

INTERVIEW WITH MR. BULLER.

A deputation from the Committee of Poor-Law Medical Officers waited, on Tuesday, the 18th instant, by appointment, on Mr. Buller, the president of the Poor-Law Commission. The deputation consisted of Dr. Burton, of Walsall, Dr. Barnett, Mr. Bottomley, Mr. Liddle, Mr. Lobb, Mr. Vallance, Mr. Lord, Mr. Ross, and Mr. T. P. Healey, the honorary secretary.

Dr. Burton, after introducing the deputation, read the resolutions agreed on by the committee, as suggestions for the remedy of the grievances now complained of by poor-law medical officers. They are as follows:—

"1. That, in the opinion of the committee, it is essential that the payment of medical officers should be by a fixed salary, exclusive of fees for midwifery and important surgical cases.

"2. That the amount of salary might justly be fixed, either by an estimate of the average of cases attended during a series of past years, considered in connection with the area of the medical district, or by the payment of a certain sum per head on the population, corrected by the consideration of the relative density and poverty of the district.

"3. That, making every allowance for the difference which must exist in the remuneration of private and public practice, it would not be just that the salary should be based on a less amount than 6s. 6d. per case, with the charge varying with the area.

"4. That medical officers of workhouses should be paid a separate salary, based on the average number of inmates, at not less than 7s. to 10s. per head.

"5. That it is just and proper, and conducive to the interests of the poor, that an extra payment should be made, as at present, for midwifery and for important surgical cases; and that it appears to the committee advisable that the fees should be paid for cases occurring in workhouses, as well as in out-door cases.

"6. That to the cases of surgery requiring payment enumerated in the general order of the poor-law commissioners should be added—

Fractures of the clavicle;
Fractures of the skull;
Retention of urine, when requiring repeated introduction of the catheter;
Severe burns and scalds;
And that £3 be paid for compound fracture of the arm.

"7. That the payments allowed for midwifery and surgical cases under the general order of the poor-law commissioners are satisfactory in amount.

"8. That in order to remove difficulties in the way of a more equitable payment of medical officers, and considering that half the union medical expenses are already paid from the Consolidated Fund, it is highly desirable that the whole expenses of the medical attendance on the poor should be removed from unions to the Consolidated Fund.

"9. That it is expedient that there be a director-general of the poor-law medical department appointed by Government, and exercising supervision over poor-law medical practice, in the manner of the other public services.

"10. That it is expedient that there should be inspectors-general of poor-law medical practice appointed by Government, and acting under the orders of the director-general.

"11. That the inspectors-general, acting each in a district assigned to them should examine the infirmaries of workhouses, inspect the reports of the medical officers, inquire into cases of alleged negligence, &c. &c., and that matters of disputed payment should be referred to them.

"12. That the medical officers of unions should be appointed by boards of guardians as at present, subject to the approval of the director-general; that their qualification should be as at present ordered, but that all future modifications of the qualifications should be made by the director-general.

"13. That the appointments of all medical officers should be permanent, that is, to endure until they die, resign, or are dismissed for some valid cause.

"14. That the forms of books or reports should be approved by the director-general, and should be as short and simple as is consistent with the requirements of the public service.

"15. That the access of the paupers to the medical officers should be made as ready as a due distinction between those who require parochial attendance, and those who do not, will admit. That in doubtful cases where illness exists, and there appears to be temporary destitution only, the board may grant medical relief by way of loan; that in such cases a fee of —— be paid by the board of guardians to the medical officer."

Dr. Burton then impressed on the president, that the grievances thus proposed to be remedied must be both numerous and oppressive, or the board would never have heard of so important a meeting as the Convention, or of so established an organization as that represented by the committee. The boards of guardians were potent, and medical men (for many reasons,) wished to stand well with them. In so many gentlemen thus coming forward, therefore, publicly to perform a disagreeable and unpopular duty, there was proof evident that the cause impelling them was no ordinary one. The workhouse attended by Dr. Burton afforded no bad exemplification: though he was better paid and treated than most persons similarly situated, his yearly stipend barely covered the expenses of the drugs and other medical appliances, and the last year it had even failed to do this; and he suggested the mischief that might arise where, from the pecuniary circumstances of the surgeon, or other causes, it would appear to him a less hardship to place the loss on the paupers, or indirectly on the rate-payers, rather than bear it longer himself.

Mr. Buller admitted that the higher cost of good medicines might act as an inducement, with some, to use them as little as possible; and he was directing his attention to that point as a great difficulty in the question.

Mr. Vallance showed that any system of drug depôts under the commission would be too expensive to succeed—a fact proved by recent unsuccessful attempts. He then enlarged on the general question of medical relief, and its hardships, especially on the non-permanency of appointments, and pointed out particularly the absurd and harrassing way in which union surgeons, as exemplified in his own case, were obliged to keep their books; he had himself ten sheets of close-ruled columns, containing each nearly thirty names, to fill up every week—work enough for a copying clerk, and deserving to be paid at the rate of the surgeon's entire salary.

Mr. Buller suggested that if so, and the committee would favour him with matured recommendations for a change, he would gladly consider them, and, if he approved of them, would adopt them. As to what had been said on the permanency of officers and the appointment of inspectors, he had already in Parliament expressed his opinion, though he confessed that the frequent change of guardians was a point worthy of further attention, in connection with permanent appointments of medical officers.

Mr. Vallance then called Mr. Buller's attention to an advertisement which appeared in one of the provincial papers, requiring a medical officer for the Cleobury Mortimer Union, who would be required to undertake the entire duties of the office, under the prohibition of not engaging in private practice, for a salary of £180 per annum, which would include payments for midwifery cases, whether common or difficult; all fractures, amputations, and vaccination, the union supplying drugs, leeches, trusses, and all surgical apparatus whatever.

Mr. Buller avowed that the advertisement was published with his knowledge and sanction; that the plan proposed in it was not wholly new, and that he was inclined to look at it without disfavour, at all events as an experiment. Great abuse occasionally occurred under the present system in consequence of some medical men ordering wine and brandy, instead of prescribing tonics; indeed, he was informed by one of the inspectors, that this course had in some instances been resorted to in cases of syphilis and gonorrhœa—maladies to which such treatment, he was told, was not quite suited.

Mr. Ross suggested that these were effects not unlikely under a ridiculously low system of remuneration, and that they evidenced the necessity of medical inspectors. He went at some length into these two questions, and was supported by Mr. Liddle, Mr. Lobb, and Mr. Lord, who insisted particularly that medical men should be responsible more to the commissioners, and less to the boards of guardians.

Mr. Buller feared that the deputation took the same view of the Consolidated Fund that was fashionable in the House of Commons. It was unfortunately not so inexhaustible as it was fancied, and in the present day was less so than usual. He confessed, however, that he entertained the inclination already avowed by him in the House of Commons, to consider medical relief a question distinct from the ordinary poor-law administration, and one which should be put on a separate and more comprehensive footing, securing efficient treatment to the poor on the one hand, and fair, if moderate, payment to the medical officer on the other. During the sitting of Parliament he was obliged more especially to direct his attention to those matters which more or less might be brought before it in connection with the poor-laws; but immediately after the sitting of Parliament it was his intention to take up the whole question of poor-law medical relief, with the hope of adjusting what he already felt was the most difficult part of all his responsibilities.

It was then impressed on Mr. Buller that, as there appeared on other general questions to be little difference of opinion between himself and the deputation, it was of great importance that he should reconsider the opinion he had given on permanency of appointments. The qualifications of medical officers were doubly tested—by the College of Surgeons and the Society of Apothecaries; if incompetent or negligent, coroners' juries would be too ready to publish the proofs: these were guarantees possessed by no other officers of unions, although the others were permanent officers; besides, the frequent changes of guardians, amounting to a new set of masters, ignorant of all that had been done and said and explained before, and some of them, perhaps, personal opponents, made the appointment during pleasure a source of constant annoyance and vexation to the independent officer anxious to do his duty to the poor fully.

It was further remarked that, as there was yet some time to the breaking up of Parliament, it would be most desirable that the committee should be allowed to bring before him, in the interval, any cases of peculiarly striking hardship, that some of the worse parts of the present system might be got rid of as soon as possible.

Mr. Buller replied that he should be at all times very happy to receive from the committee any such communications; that he would not fail to give them his best attention, and that he should be obliged by any information the committee would favour him with on the subject of their interview.

After some further conversation, in which Mr. Buller repeated his impression as to the policy of a distinct organization of medical relief, the deputation, through their chairman, expressed their thanks for the marked courtesy with which he had heard their representations during a very protracted interview, and withdrew.

PRINCIPLES OF MEDICAL LEGISLATION: REPLY TO MR. NUNNELEY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

A letter is published in the *Provincial Journal*, of April 19th, from Mr. Nunneley, of Leeds, in which that gentleman animadverts upon the "Principles" of Medical Legislation, recently agreed to by the conference held at the Royal College of Physicians, on the ground that they are at variance with the deliberate and frequently recorded opinions of the Provincial Association.

Not having the honour of belonging to the Association, I may be but partially acquainted with its views, and I believe I am entitled by courtesy only to appear in your pages, so that I shall feel myself particularly obliged if you will give insertion to a few remarks on the statements contained in the letter referred to, confining myself, as respects your Association, to such of its opinions as are therein set forth.

Mr. Nunneley quotes three principles of the Provincial Association, with which he states the principles of the Conference are at variance:—1st, uniformity of the primary qualification—more generally understood as the "one portal" scheme; 2nd, equal right in every member of the profession to practise throughout Her Majesty's dominions; 3, the representative system in the formation of the governing bodies. For convenience, I will take these in the inverse order in which they are enunciated.

Firstly.—As respects representation, the principles now at length agreed upon by the College of Physicians, the College of Surgeons, and the general practitioners, as represented by the Society of Apothecaries, and the National Institute, embrace the resignation of the professional powers and privileges of the Society of

Apothecaries, and the substitution of a new college, in which every member will equally and alike be possessed of the right of representation; in other words, the institution of a representative College of General Practitioners in medicine, surgery, and midwifery, in place of the existing Society of Apothecaries, the licentiates of which have no electoral or corporate rights or privileges whatever.

Mr. Nunneley is a *Fellow* of the College of Surgeons, and as such, is possessed of the right of representation; he knows well that nine-tenths of the general practitioners are not fellows; that they cannot become fellows; that the attainment of the right of representation in that College by the *members* is totally impracticable, and that, accordingly, this large body, numbering thousands, are at present deprived of all right of representation. If representation in the governing councils is an admitted principle of medical reform, how can Mr. Nunneley repudiate a representative collegiate establishment, which will embrace by far the greater part of the profession, hitherto, from time immemorial, and at this moment, totally unrepresented?

Secondly.—Equal right of practice is also a principle of the Association. The principles of the Conference state, (Art. 5,) "That the members of each class of the profession registered in each of the three kingdoms respectively, should be entitled to be registered and to practise reciprocally in either of the three kingdoms as physicians, surgeons, or general practitioners, as the case may be, *provided the education and examination of each class respectively be assimilated and regulated by a certain standard common to each class.*

How can Mr. Nunneley assert in face of this that the principles of the Conference contemplate "no uniformity of education," and are thereby at variance with the principles of the Association? Why, sir, they contemplate the nearest approach to uniformity practicable, for at least nine-tenths of the profession, together with absolute uniformity of privileges in every part of the kingdom. If Mr. Nunneley means to say that the Conference has not provided that the education of the physicians shall be uniform with that of the general practitioners, he is so far correct; but it should be borne in mind that the representatives of the physicians in the Conference could not be expected to be parties to any measure, the direct object and the immediate effect of which must be to "strand" that College, to sever its University connection, and to destroy it as an Institution.

Thirdly.—As respects the "one portal" scheme, the principle of the Association is "uniformity of the primary qualification, to be tested by sufficient examination." The principles of the Conference embrace, as I have already shewn, uniformity of qualification for nine-tenths of the profession over the whole united kingdom. The one is not *at variance* with the other—it is the identical principle. All that can be said is, that the principle is not made to apply to the remaining tenth part of the profession. I have no hesitation in saying, that if Mr. Nunneley, as a Fellow of the College of Surgeons, can persuade the Council of that College to make every candidate educated to obtain the Fellowship at 25 years of age, pass the examination for the Membership at 22 years of age, for my own part, I think it would be an improvement upon the principles; but I do not believe this to be a point of so much consequence that we are to sacrifice everything for it. As respects physicians, there are real, if not insurmountable, difficulties connected with the course of education which the College feels it incumbent to lay down, and I do not believe Mr. Nunneley would confer any boon on the profession if he were to succeed in persuading the College of Physicians to forego, on the part of their candidates, a University standard of education in languages, mathematics, and literature, in order to give physicians the legal title to practise at 22 years of age.

Thus much respecting the appeal of Mr. Nunneley to the principles advocated by the Association. The writer, in common with many other gentlemen, is under a great misapprehension respecting the powers of the proposed new College. I am glad of the opportunity to state that the evidence given by my excellent colleague before the Parliamentary Committee is literally correct, notwithstanding an apparent discrepancy between his evidence and that given by the President of the College of Surgeons. The Conference unanimously agreed, both before and since Mr. Bird's evidence was taken, that the new College is to have the unfettered right of examining in medicine, surgery, and midwifery, and on any and every subject which the Council may deem essential to test the qualification of the candidates to practise as general practitioners of medicine, surgery, and midwifery.

The operation of the Act, if it should be obtained, will be as I take it, that a uniform curriculum for the education of the general practitioners in the three kingdoms must be laid down, under the sanction and approval of the Council of Health, that the examinations will be made to assimilate as nearly as possible, and that reciprocity of practice will be secured.

Mr. Nunneley is one of the *Honorary* Fellows of the College of Surgeons, selected by an arbitrary rule from the members at large, and he states in his letter that the new College "must inevitably be of the lowest grade." By this assertion he imputes inferiority to those members of the College who were not selected for the Fellowship, and to the great body of the general practitioners of the country. I have seen a similar imputation in editorial articles, and in many anonymous letters, bearing the most heterogeneous signatures, but affording internal evidence of a common parentage, and have never deemed such productions worthy of the slightest attention. The imputation coming, however, from a gentleman of Mr. Nunneley's respectable standing, induces me, to state fearlessly, that the general practitioners of this country, in their individual capacities, are as truly respectable, possessed of as high talents and acquirements, as zealous promoters of science, as sound practitioners, and have as great and as just a hold upon the public confidence, as any other class of the profession. Who, then, shall say that in their associated character they are less respectable, less competent, or less zealous, or that when incorporated into one body politic, they must necessarily be an *inferior incorporation*? I willingly acquit Mr. Nunneley of a deliberate intention to offer a direct insult to the majority of his professional brethren; but let us hear no more the *cuckoo cry* of *inferiority*,—it is especially ungracious as coming from an *Honorary* Fellow of the College of Surgeons.

On the subject of an effectual penal enactment:—Some years ago, an article was written in the *Quarterly Review*, by an eminent surgeon, and a pamphlet was published about the same time by an eminent physician, in which it was attempted to be shewn by the one, that "protection," is *inexpedient*; by the other, that it is *impracticable*. The influence exercised by the authors of these productions over successive Governments, and the effect of the articles themselves on the members of the Legislature and the literary classes of society, and even in the medical Corporations, have no doubt thrown great impediments in the way of such an enactment. Mr. Nunneley appears also to have imbibed the doctrine that it ("protection,") would be neither practicable nor expedient; but I believe him to be at direct issue with the majority of his professional brethren on this point, who deem an efficient penal enactment *practicable, just,* and *necessary*. I feel convinced that the profession at large will consider that a great step has been made towards the attainment of this object by the corporate bodies of this country having admitted the necessity of such an enactment in the principles which they have unanimously agreed to and promulgated. The profession is aware of the difficulties which surround the question, but so far from viewing it in the light that Mr. Nunneley does, "that protection is more and more growing into disrepute," and so far from taking his advice, "to depend upon its not being carried," I see several Acts of Parliament just completed for the protection of life and property; I know that others are contemplated by the present Government for the protection of the health, limbs, and lives of Her Majesty's subjects; and I believe that if the profession cordially support the principles of the Conference, very effectual checks to illegal and unqualified practice may be secured.

I agree with Mr. Nunneley that a principle cannot be *compromised*, and that it ought not to be *abandoned*. I trust I have shewn that the Association will neither compromise nor abandon either of the principles set forth in this gentleman's letter by adopting the principles of the Conference; and I may be permitted here again to say, representation either is, or is not, a highly desirable thing; if not, the question might be asked, why does the Provincial Association put it prominently forward as one of the first principles for a measure of medical reform, or why does Mr. Nunneley quote it as such? If it is really what we have ever been taught to believe, the only means by which any very numerous body of individuals can carry into effect their legitimate objects of amelioration and improvement, why should Mr. Nunneley, being in possession of it himself, seek by his appeal to the Association, to prevent the enjoyment of it by the majority of his professional brethren?

I unhesitatingly affirm, in conclusion, that a College founded on the representative principle, which shall comprise the general practitioners of this country, and possess the powers contemplated by the proposed Charter, will be inferior to no institution of a similar nature in this or any other country.

I have the honour to be, Sir, your obedient Servant,

HENRY ANCELL.

3, Norfolk Crescent, Hyde Park,
April 28, 1848.

Medical Intelligence.

ASIATIC CHOLERA.

The Registrar-General, in this week's return, narrates a death occurring from this formidable malady in the East-end of London, after five days' illness. There will, probably, on further investigation, be found some mistake in this statement; but, coming from such high authority, there is enough in it to justify this brief notice, in order that the attention of practitioners may be awakened in this direction, if the report should, unfortunately, prove correct.—*Medical Times*, April 29th.

APPOINTMENT.

James Miller, M.D., Professor of Surgery in the University of Edinburgh, has been appointed Surgeon in Ordinary to Her Majesty the Queen in Scotland, in the room of Mr. Syme.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, April 14, 1848:—R. Woodman; F. F. Ladd; W. Hoggan; F. E. Goldsmith; J. S. Leeson; T. W. P. Jago; F. F. Barkway; G. W. Mackenzie; W. Webb.

Gentlemen admitted Members, April 28th:—C. King; R. Stewart; J. F. Smith; H. P. Leech; S. T. Fearon; J. H. Brownfield; S. F. Statham; J. W. Parry; R. Mc'Nicoll; A. B. Sharp; J. B. Hayes.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates Thursday, April 13, 1848:—Thomas Jeston, Henley-on-Thames; Benjamin Buck, East Dereham; Charles Worth Pearce, Leeds; Henry Tineman, York; Thomas Alcock, Cheshire; Charles Martin, Stockton; William Thomas Holme Burrow, Settle; Joseph Gustavus Symes, Crewkerne; William Birds Wall, Liscard, Cheshire.

Thursday, April 20th:—Thomas Alderton, Shotley, Suffolk; Richard Colthurst, Bristol; James Kidd Dow, Islington; Charles Hanlen Gamble, Barnstaple; Thos. Brideoak Knott, Lees, near Manchester; Henry Thos. Spratt, Bermondsey.

OBITUARY.

Died, April 5th, at Finglas, aged 37, of fever, Charles Le Grange, Esq., L.R.C.S.I., Medical Attendant of the Finglas and Glasnevin Dispensary.

April 7th, at Brixton Hill, Streatham, aged 26, Henry Edward Cullen, Esq., Surgeon.

April 7th, at Ballyshannon, aged 30, of fever, — Stephens, M.D., Medical Superintendent of the Kinlough Dispensary.

April 14th, at Teignmouth, John Spens, M.D.

TO CORRESPONDENTS.

Communications have been received from Dr. Bullar; a Midland Counties' Surgeon; Mr. Ancell; Mr. J. S. Bartrum; Dr. Carey; Mr. H. Williams; Dr. Oke; Dr. Wardell; Mr. W. Collyns.

PROVINCIAL
MEDICAL & SURGICAL JOURNAL.

REMARKS ON THE PRESENT ASPECT OF MEDICINE.*

By W. Newnham, Esq., Farnham.

It is perfectly true that medical persons often gain credit for cures which nature has performed, and which they have been too indolent to attempt; and it is equally true that they suffer oftentimes a great deal of discredit, for cases in which nature, seconded by art, has failed, and upon which they have bestowed the utmost energy of their powers, their research, their experience, their full thought, their deep anxiety;—and that simply because the malady was in itself incurable, or had been negligently allowed to obtain such a hold upon the constitution as to render it impossible to be overtaken; and while we bear the one without murmuring, it is scarcely to be expected that we should have moral courage sufficient to disclaim the apparent compensation afforded by the other. In medical practice there is not such a preponderance of pleasing circumstances, as to enable us willingly to quench even the fitful sunshine of an April day.

It is equally the fact that medical men, as they grow older, become more distrustful of results; the enthusiasm of their early years is abated, and they become less "heroic" in their prescriptions, more trustful of nature, less confident in themselves. In proportion, too, as they shall have been imbued with the practice of our continental neighbours, they will see abundant reasons for diminished activity in the use of the lancet, and mercurials, and other violent means. The effect of this natural process may be good or evil. If parties shall have been enthusiastic students,—almost believers in the omnipotence of medicine, the effect will be good; their enthusiasm will be exchanged for zeal, and their practice, without abating of its energy, will lose somewhat of its temerity; their expectations will have been reasonably sobered; and they will become admirable practitioners. But if they shall have commenced life in the spirit of business, with less benevolence, and less enthusiasm, and less interest, the moderating influence of time will act injuriously; the little interest of first love cannot suffer abatement without irreparable injury; and they will become sceptics in the power, and inert in the practice of medicine. They will shelter their natural love of ease and indolence, under the pretext that nature must be allowed to have her own way; that she is the only real physician; and that we only disturb her agencies by interference; and thus become criminally careless of human life, always flattering themselves that they are consulting the good of mankind by doing nothing. And yet, it is manifest that they pursue the *post hoc propter hoc* argument in its most erroneous possible form. Certain individuals have been affected by certain maladies; nothing has been done for them, and they have recovered; therefore, they have recovered *because* nothing was done for them. Thus, the advocates of natural cure have no other ground to stand upon than that which they attribute to their less passive brethren, but which judicious medical persons abjure. It is freely allowed that the specific diseases are not to be interfered with; that they must run their course; that fever also is not to be strangled at once; and probably, that many other maladies may have their course; and that in such cases, the department of medicine consists in carefully watching any organ or function of the body which may especially suffer, and in applying a remedy corrective or palliative for such disorder. Yet, this by no means justifies a reliance upon nature exclusively; it is only that her own curative processes are not to be violently and carelessly interfered with, and that wherever these are excessive, or defective, or erroneous, or threatening, there is the dominion of art to be called up.

It is curious that in his zeal against the influence of the *post hoc propter hoc* treatment, Dr. Forbes should have adduced in illustration, a case which has no other ground to rest upon than this very *post hoc*. The case of a little girl, admirably described for effect, who had been under his care in a dispensary, and for whom he had prescribed according to the most approved rules of art, with "its basis, its adjuvans, its dirigens, its corrigens, and its constituens;" and who, at his visit, reported that she had been well since *Friday*, and that because her "medicine was done" on that day. Now, we verily believe that Dr. Forbes never wrote a prescription with a view to these especial *ingredients*, and, therefore, while we fully admit the bare fact narrated, we cannot be blind to the truth, that it has been dressed up to serve the particular occasion. But, supposing the whole to be a true, and faithful, and unadorned representation, what is the fair inference? Is it that the girl was well *because* she had left off her medicine since Friday? This would be simply *post hoc propter hoc*. Is it that nature had effected the cure in spite of the medicine? This would not be borne out

(* Continued from page 229.)

by the circumstances. Or is it that nature, aided by the medicine, had completed the cure a little earlier than the doctor's prescience had anticipated? This again would be *post hoc propter hoc;* and, at any rate, the case adduced to throw ridicule upon this very absurd mode of reasoning, is itself an instance of that same reasoning.

Fully admitting the absurdity of the *post hoc propter hoc* argumentation, we yet think that more has been made of its absurdity than it deserves, and we wish clearly to point out that the converse of the proposition is equally absurd and untrue; the inference drawn *may* be just, but as a general rule it is unspeakably absurd, however useful as a weapon of sophistical warfare, *post hoc, ergo non propter hoc.* Here there is no reasoning at all, whereas the man of science who, from his previous knowledge of the laws of healthy function, and morbid action, and of the agency of medicine upon these respectively under given circumstances, selects a remedy which he believes calculated to produce a certain effect upon the present disorder of the system. When he perceives that this effect is produced, and when after repeated trials he finds similar results, he does rationally arrive at the conclusion that the latter is the consequent of the antecedent. It is upon evidence of this kind that rational medicine is founded, and Dr. Forbes must have been singularly unhappy in his cases, in his selection of remedies, or in his judgment of the disease to which they were supposed to be applicable, if he have not for ever and for ever found exactly the effect he calculated upon. And if this so calculated effect be not produced, it is because the remedy has been badly chosen,—or sufficient discrimination has not been employed with regard to the disease,—or there has been *too great simplicity* in the prescription,—or there has been some other error, which may prove the fallaciousness of our judgment,—or our indolence,—or our want of tact,—or the necessity for more attention and study, but by no means shews the inefficacy of medicine.

We have mentioned the *too great simplicity* of the prescription, because Dr. Forbes seems to lay great stress upon this simplicity. Now, cordially averse as we are from the system of prescribing for symptoms, and of putting into our remedies a little of everything, in order that each apparent disturbance may get something for its peculiar phenomena, yet we do think, and are sure, that the efficiency of medicine depends greatly upon judicious combination. For so long as there is no simplicity in morbid action,—so long as the body is composed of a set of mutually dependent organs and functions, the disturbance of one of which involves the disturbance of the whole,—and so long as we possess classes of medicine capable of acting especially upon one or other of these organs and functions, so long will the efficacy of means, and the success of treatment, be dependent upon the judicious combination of medicine. Everybody in much practice is aware of this circumstance: give a single remedy, and you produce no effect, or a part only of what you wish,—combine it, and you not only obtain the peculiar action you require more efficiently, and at less cost to the system, but you further act upon other organs and functions, the restitution of which to their normal condition is necessary to health. Examples of these facts cannot be required; they must be familiar to every observer, and it would seem that the great art in medicine is a deep study of this judicious combination,—not a throwing together of many heterogeneous materials, but a selection of several, all bearing upon certain great scientific indications.

It is perfectly true that as practitioners grow older, they become less confident in heroic measures, but they become more confident in the means they do employ, and they do not lapse into that inertness which leaves the patient to the unaided efforts of nature. We have before stated the common reasons for this inertness as arising out of mental constitution, natural indolence, defective judgment, or moody disappointment. This class of expectant practitioners will stand by and witness nature's own unassisted efforts, and from day to day will sooth their consciousness with the hope that the patient is not worse, and with their oracular apothegm, "Non regredi est progredi," forgetting that this is but a *post hoc propter hoc* argumentation, and that it is met at once by its crushing converse "Non progredi est regredi."

One word on the desirableness of the natural history of disease. Alas! that we have already too much of this natural history. How perpetually are we consulted by patients, who have allowed disorder to run on unchecked in their constitutions, till it has passed the reach of art to overtake! How perpetually are we grieved by being asked to prescribe for patients whom we know full well we should in all probability have restored to health by an early application of remedies, but to whom attention is now hopeless! How perpetually do we see disorder, unchecked, run its *natural* course to the extinction of life on the one hand, or checked by science, and life and health restored on the other! We may be told that we have no good ground for this assertion, for that what is *post hoc* is not *propter hoc.* At any rate there is the same reasoning for medical treatment as for natural agency: both stand on the same footing; and since in serious malady the one very frequently terminates in the destruction of life, and the other very frequently in recovery, it is cruel, it is unjnst, and a grievous dereliction of duty, to allow morbid action to go on where it *can* be arrested, for the sake of *obtaining a natural history of disease,* which is at all times sufficiently obtained by watching its progress, notwithstanding the means judiciously employed to avert its disastrous consequences. This of course supposes that the means have been *judiciously* chosen: we are not prepared to say that they always have been so chosen; we are not prepared to say that they may not have been ill-chosen in a great majority of instances: but this, if granted, is not an argument against the employment of medicine, though it is an argument for the improvement of professional character, and above all, of that preliminary education which has the principal influence in teaching to think clearly,—to discriminate justly,—to compare accurately,—to combine with discretion,—to judge rightly,—to decide fairly,—and to act *fearlessly*, though not *rashly.*

We have said enough of the *post hoc propter hoc principle*, but we must notice a little further its practical application. Our author has argued that homœopathy and allopathy rest on the same ground, and appeal to the same success, as the consequence of their means; and since homœopathy is not true, and allopathy is only partially true, we must explain both upon a third power common to each,—viz., the power of nature, which in these instances effects the cure. Grievously as such views must paralyse exertion, and close up the avenues for inquiry,—and stunt the human intellect,—and wither investigation,—and blast every object for advancing pursuit,—we are particularly anxious to show, that while we would invite and watch the powers of nature, we dare not leave her to her own resources; for perpetually does nature overact her part, or fail in its due performance; and in either case she requires to be controlled or aided. Besides, it is not true that homœopathy and allopathy stand upon the same ground, or that they possess only similar claims to attention with Parr's life pills, and other similar remedies. It is easy to understand how a succession of new patients may be found for these novel and unknown and mysterious remedies;—it is easy to understand how the slightly indisposed, or the fanciful patient, may recover; and how the really serious invalid may conceal the memory of his injuries in the grave, thus leaving the recovered to sing the praises of the remedy, and the destructive agency of "trusting things to nature," to be concealed by the art of the undertaker. But such cannot be the case with legitimate medicine; there is no mystery-loving agency here,—there are no high-sounding pretensions, nor alluring advertisements, but results stand on their fair basis. With regard to homœopathy itself, there is a great deal of this mysterious agency at work, and before its statistics of a few years can be placed in comparison with the experience of medicine of 2000 years, there must at least have been time for the subsidence of that prestige in its favour, which enthusiasm in support of its mysteries, and the general self-love engendered by the individual power of every body equally to cure diseases shall have subsided;—and then might a comparison be instituted,—and then might it be inquired, if there be any power or principle common to both which might be adduced to explain the results. It is obvious that none such now exists, and therefore all attempts must fail to convince that homœopathy cures by the powers of nature,—that allopathy obtains the same results with homœopathy,—and therefore that both *cure* by a common power, even the power of nature. All bounteous Nature! from this time forward are we to trust to thy powers? Then no more let us plough our grounds,—or sow our seeds,—or plant our gardens,—or prune our trees,—or manure our soil;—but let us trust to thine unassisted powers;—let us first of all obtain a natural history of thy rude growths, and not till then dare to interfere with thy productions!

We are fully disposed to admit that the treatment of disorder by medicine is oftentimes *inefficacious*, and sometimes *injurious*;—nay, we can believe with Dr. Forbes, that the rapid cure of some patients under hydropathic or analogous treatment, may depend upon their abandonment of injurious medicine. But we place on the opposite side of the question, the awful ravages of uncontrolled disease, and the deaths, and frightful disorders mental and bodily, produced by hydropathy. We will take our disputant into the cottages and hovels of our land, where he shall see disease and destitution; we will take him among the wealthier classes of society, yet still among those who, from some circumstances have not had recourse to medical aid; where disease shall have pursued its unchecked course, and where his sympathies shall be called into exercise, over maladies which in their origin might have been averted, but which now too surely convey the sufferers to a premature death: and admitting in its fullest force, that some *mischief* is effected by injudicious medical treatment, yet this is nothing when compared with the irremediable evils presented to the mind, of uncontrolled malady constantly pursuing its relentless course, because it has not been *early* arrested. "Obsta principiis,—sero minus medicina paratur." Place the two evils in opposite scales, and the one instantly kicks the beam. But even without this comparison, what is the value of the argument to be drawn from the evils induced by injudicious medical treatment, and the good arising from its abandonment? Why surely *not* that *medicine* is an evil, or its disuse an advantage! But simply that the study of medicine requires more attention,—and that the practice of medicine demands further improvement,—and should be placed under the control of minds adequately prepared, and properly constituted for this great object. We shall notice in the sequel, some of the more prominent evils which require abatement.

Surely it is not extraordinary, that the inmates of hydropathic establishments, after having had their prejudices against medicine loudly and largely excited, should retain those prejudices in after life,—should cherish the horror of drugs thus imbibed, and should if possible avoid them for ever! Who, that is conversant with the human mind, and with the strength of its prejudices, can be surprised at such effect on persons incapable of forming a correct judgment upon the subject? Who, that is acquainted with the history of mental obliquity, and is not thoroughly aware that it is useless to argue against prejudice, because it has no ear for reason,—no eye for demonstration,—no taste for truth,—no perception for right, but remains unapproachable within its own self-created narrow circle, and most religiously believes that beyond its magic influence, there is *nothing to be known, because it knows nothing!*

With regard to those older physicians, who have abated much of the energy of their early practice in after life, and who could boast that they had been curing their patients with "nothing at all," we can certainly conceive of such a result in certain indolent minds,—or in in those who, disappointed in their too sanguine expectations, have naturally enough rebounded to the conclusion that there was *nothing in medicine*—a revulsion of feeling very common with the human mind, enthusiastic to extreme in its first love, gradually abating in that love till it has passed through

indifference to aversion; and now the zealous devotee has become the bigotted persecutor, and the purblind admirer has lost his senses in the intoxicating charms of another seducer. But the evil does not rest here; for not only has the faithful enthusiast become a sceptic and a bigot, but alas! for his moral standing, he has become a *hypocrite;* for with his belief that medicine is useless,—with the fact that he is doing nothing for his patients,—that nothing is required to be done,—and that the veriest old woman in the world will prescribe as successfully as himself, he has still gone on to prescribe, and to receive his patients's fees,—a depth of delinquency, which throws the air of doubt over his whole conduct! To physicians entertaining such views, nobody would send a patient if they could avoid it; and they are called upon to abjure and renounce all connection with medicine, or its study, or its literature, for of what avail is it, if it be useless?

Our author thinks that we shall by-and-bye obtain a true natural history of disease by means of homœopathy. We think *not;* because, first, in patients who submit themselves to homœopathic plans, a very great effect is produced upon their nervous system,—a very large proportion of faith is developed; hope is cherished in an extraordinary manner, and the attention is so rivetted upon the strictness of the method of treatment, that it is impossible but that the nerves of intellectual and organic life should be largely impressed and excited, and that this impression and excitement should be all on the cheerful side,—all tending to restore health to the body, and therefore exerting a large and extensive influence upon all the functions of life. Moreover, a direct medicinal effect is produced by an altered and peculiar diet and regimen,—an effect analogous with that produced by medicine in a different way. In fact, regimen is another form of medicine; it need not be called physic, but it is so, and exhibited, if wisely given, to fulfil the same indications. If then, through homœopathy, a large impression is exerted upon all the functions of life primarily, and, secondly, by the regimen inculcated in lieu of other medicine, it is clear that a disturbing agency is effected upon the morbid actions of the body, and that it is useless to look for a natural history of disease through the vista of homœopathy, however long the experiment may be conducted. The only *natural* history of disease which we can obtain, is that fatally instructive one, so frequently placed before our vision, of malady, pursuing its destructive course, till shrouded from our sight by the night of the grave. Well indeed for our own peace, if we have not been accessary to this grievous conclusion, by our own criminal negligence, and apathy, and listlessness.

It is freely allowed that the history of medicine is one of perpetual change, and the fact is *partially*, but not *entirely*, to be regretted. This change is dependent sometimes upon the increase of knowledge, and juster and sounder views of disease and its treatment; it is sometimes dependent upon the introduction of new and valuable remedies, or upon the supersession of long cherished errors and prejudices; it is sometimes dependent upon the altered character of disease, a fact probably arising from the epidemic constitution, of the atmosphere, and which has been noticed by that great master of our art, Sydenham; and it is sometimes dependent upon closer research, and novel discovery. In all these cases change is beneficial; but even here the benefit is much alloyed, by the change becoming fashionable; it is taken up by everybody, and carried out in its extreme bearing, losing every feature of its original constitution, and then becoming injurious. At other times this change shall have been effected by prejudice, arising from a very narrowed sphere of observation; yet ushered into notice by the authority of some great name, it is supported and carried out till it is found to be useless and injurious. So the present extension of homœopathy, and the undue exaltation of the curative powers of nature, is only another change,—another wild offset, from the wild stock upon which medicine has been grafted, but which will never tend to produce good fruit, because its tendencies are all the other way,—to exalt ignorance upon the same pedestal with science,—to repress investigation,—to stunt the human mind,—to convert practitioners of medicine into exhibitors of globules,—and to transmute the man of science into a meek helpmate of the culinary and murky denizens. The whole world is one perpetual scene of *change*; the charge of mutability is not confined to medicine; in all but the fixed sciences, who can reckon upon the doctrines of to-day surviving the discoveries of to-morrow? Who can find fault with the changes which have taken place during our own life, (almost a sexagenarian,) in chemistry, botany, natural history, geology,—changes so great as to make these sciences new sciences, and requiring to be re-studied by those who have not kept their knowledge up to the advancement of the hour? Change is not essentially an evil in itself; it ought to be an improvement; and we have no right to complain of change in medicine; all we have to care for is, that the change should be in the right direction, and not retrograde,—not in a line which will finally terminate in the gloom of the darkest ignorance, and in the aberration of asserting that it is *perfect light*.

We have lived to see the high reputation of antimony, blood-letting, and mercury, for the cure of fever, pneumonia, and syphilis;—we have lived to see epidemics of fever which must be variously treated according to their peculiar constitution;—we have lived to witness doctrines and practices change;—we have lived to change our own, and, we venture to hope, to discriminate better when to give and when to withhold our more active agencies; but amidst all the turmoils of these conflicting elements, we venture to say, that we in common with all other observers, have also lived to see the time when bleeding, and antimony, and mercury, can be judiciously given, and to reap decided good from their employment to-day, and equally decided advantage from withholding them to-morrow, according to the circumstances.

But with regard to *mercury*, there are perhaps few, very few, who have witnessed its surprising influence over disease, and who have not been at the outset of their career enthusiastic in their employment of this

medicine. It is only after they have discovered that it does not always do good,—nay, more, that it sometimes does harm,—that they become discriminative as to the time and the dose, and the manner in which it ought to be exhibited. It is then only they will have discovered that it is not every case of inflammation which requires mercury for its cure, and that they cannot in every instance rely even upon it;—it is then only they will have discovered the importance of mercury, judiciously, boldly, yet prudently administered, when inflammatory action has to a certain extent been controlled by other means, and when by the establishment of a new mercurial action in the system they will thoroughly supersede the morbid action, or control and remove its morbid sequelæ;—it is then only they will have discovered those cases and those stages of disease in which they can pronounce the patient safe so soon as they can trace the smallest influence upon the gums;—and it is then they will have discovered the lamentable consequences of leaving these cases to their *natural* terminations. The influence of age and experience upon the exhibition of this remedy is not that we become averse from giving it, but that we know better when to give it, that we become more cautious in its mode of administration, and that we give it perhaps in one case out of ten of our early exhibitions; but that whenever we do give it, we give it fearlessly though prudently, and in perfect confidence of its beneficial influence. These are the observations of an old man, of one who has abated nothing of his early enthusiastic love of his profession, and one over whom 35 years of active practice have not diminished his confidence in medicine judiciously employed, have not lapsed him into the inertness of dozing expectancy, but have, as he hopes, extended his means of usefulness, and enabled him to become acquainted with the spirit of the motto adopted as an armorial ensign by one of his progenitors—"*miseris succurrere disco.*" In saying this, he would strongly deprecate the egotistical phrasiology, too common in the professional world, of saying, "I have cured this and that malady by this and that treatment;" and while he has frequently seen the results he was endeavouring to obtain, he would always hope to feel that he was an agent in the hands of Providence for bringing out His merciful designs; that he was eminently responsible for the active and intelligent employment of every portion of the talent entrusted to his care; and that while thus truthfully, zealously, and honestly devoting his powers to the welfare of his patients, he was not answerable for results, but might confidently expect that the general issue of his labours would be in some portion of the blessings diffused by Infinite Goodness and Mercy.

(To be continued.)

SHORT NOTES OF THE OPINIONS AND PRACTICE OF THE LATE JOHN PEARSON, ESQ., F.R.S., ON SYPHILITIC DISEASE.*

By W. S. Oke, M.D., Physician to the Royal South Hants Infirmary.

Eczema continued.—Eczema, although produced, is not always aggravated by mercury, and there are some few cases in which there has been a recurrence of the eruption without any more mercury having been employed, coming on five or six weeks after a mercurial course.

When a patient has returned to the use of mercury, after perhaps a week's intermission, there will occasionally be a slight redness of the skin over the whole body, unattended by vesications, yet terminating by desquamation.

Eczema mercuriale does not resemble any other eruption produced by mercury on the skin, and, therefore, there is no difficulty in the diagnosis. Mr. Pearson never knew the disease to prove fatal, nor has he ever seen it in any patient above 50 years of age. He became first acquainted with this disease in the year 1781.

[*Vide* "Observations on the effects of various articles of the Materia-Medica, in the cure of Lues Venerea." Second edition. Page 167.]

Treatment of Eczema Mercuriale.—When the eczema has affected the skin partially, it is not always exasperated by persisting in the use of mercury; nevertheless, there are reasons sufficiently obvious to render the continuance of this medicine improper when the whole surface is infested with it; as a general rule, therefore, the administration of mercury must be discontinued on the first appearance of the eruption. At an early period, small doses of antimonial powder may be taken, with saline medicine; a gentle purgative should be given every three or four days, and opium may be administered to allay irritation and procure sleep.

When the discharge is no longer ichorous, and the tumefaction is subsiding, sarsaparilla and bark may be given liberally; the dilute sulphuric acid also will sometimes be found beneficial. The diet is to be light and nutritious; but it is not generally advisable to allow of fermented liquor, till the desquamation of the cuticle is somewhat advanced.

The misery arising from the irritation of the skin may be greatly alleviated by strict attention to cleanliness, the warm bath, and changes of linen. Where the warm bath cannot be conveniently used, the body may be washed with warm water-gruel once or twice a-day.

Those parts of the surface where a separation of the cuticle has taken place, may be covered twice a-day with linen rollers of different lengths, thickly spread with a soft mild cerate, consisting of litharge plaster, yellow wax and olive oil.

* Continued from page 232.

[As the *treatment* of eczema, and the whole account of erethismus are omitted in the MS. from which these notes are taken, I have thought it right to supply the deficiency from Mr. Pearson's work above quoted. It is satisfactory to know that the brief description of eczema, taken from the MS., so completely accords with Mr. Pearson's published account of the disease, as to leave no doubt of its authority.]

*Erethismus Mercurialis.**—This kind of erethismus is to be ascribed to mercury acting as a poison on the system, quite unconnected with its agency as a remedy; and its deleterious powers are neither in proportion to the inflammation of the mouth, nor to the actual quantity of the mineral absorbed into the system.

It is characterized by a great depression of strength, a sense of anxiety about the præcordia, irregular action of the heart, frequent sighing, trembling, a small quick pulse, pale contracted countenance, and a sense of coldness. The tongue is seldom furred, nor are the vital or natural functions much disordered.

When symptoms such as these are present, a sudden exertion of the body will sometimes prove at once fatal.

To prevent the dangerous consequences of this diseased state, mercury ought to be discontinued, whatever may be the stage, or extent, or violence of the venereal symptoms. The impending destruction of the patient forms an argument paramount to all others. The patient must be exposed freely to a dry cool air, in such a manner as shall be attended with the least fatigue. It will not be sufficient to sit with the windows open, he must be taken out into the open air, and remain there as much as possible until the fore-mentioned symptoms shall be abated.

The good effects of this mode of treatment, conjoined with a generous diet, will soon be manifested; the patient will be so far recovered in the space of from ten to fourteen days, that he could safely resume the use of mercury; and what may appear remarkable, he can very often employ that same specific efficiently afterwards without suffering any inconvenience.

In the early stage, indicated by paleness of the countenance, inquietude, frequent sighing, short respiration, constriction across the thorax, a sense of fluttering at the præcordia, and a small, quick, and often intermitting pulse, the further progress of the mercurial erethismus may be frequently prevented by large doses of volatile alkali in camphor mixture; and the patient will be subsequently benefitted by the free use of sarsaparilla, given either in powder or decoction.

[The following case of mercurial erethism occurred in my own practice:—A gentleman, of middle age, and captain of an hussar regiment, consulted me for an obstruction of the bowels, derived apparently from a torpid and disordered condition of the hepatic function. Three grains of calomel, conjoined with five grains of the compound extract of colocynth, were ordered every two hours, till the bowels should be freely moved. After he had taken about four doses without any satisfactory alvine evacuation, I was sent for in great haste, as he appeared to be sinking. On my arrival I found him greatly depressed, pale, pulseless, and sighing, with remarkable inquietude, and pain of the feet—in short, it was evident that the mercury had brought him into an alarming state of erethism. The windows were thrown open, and warm brandy and water and the volatile alkali were freely given. From this treatment he speedily recovered from the erethismal depression, and with the use of other aperients got well.]

Management of Patients under Salivation.—It sometimes happens that mercury is determined to the mouth in a degree beyond what is wished or expected, and that when only a small quantity of mercury has been used. One drachm of mercurial ointment has brought on a salivation which lasted four or six weeks; and a single dose of calomel in children will sometimes produce a ptyalism, which threatens life. [Such a result in children I believe to be extremely rare; but I have seen three cases of salivation in adults, all at an advanced age, which terminated fatally from gangrene.]

Patients under salivation should breathe a free, warm, and dry atmosphere: a moist atmosphere should be studiously avoided. They need not to be confined to the house, but should be exposed freely to the open air.

When the tumefaction of the throat and cheeks is considerable, the mercury should be immediately laid aside, and the ointment washed from off the body.

It happens occasionally, when mercury has been taken or used for a few days without any visible effect, that both the mouth and bowels become suddenly and violently affected. The patient has frequent stools, with much pain in his bowels, and a remarkable depression of strength; or there may be distressing tenesmus, or copious stools, without much griping. Under these circumstances it is also necessary to suspend the mercury at once.

Accumulations in the bowels is the most common cause of these symptoms, and should be guarded against; when, therefore, there is tenesmus without dysentery, it will be right to purge the patient smartly once or twice: unless this is done, opiates and astringents will only be unsuccessful and injurious. If, however, there are copious stools, which threaten exhaustion, opium may be given with advantage.

There will sometimes be a premonition of the coming on of a ptyalism a day or two before it appears, by a fulness and tenderness of the throat, fauces, or cheeks, or perhaps of only one cheek, and then the patient should be purged, put into the warm bath, and exposed to the open air.

There is no specific mode of treatment in salivation.

* A morbid state of the system, named and described first by Mr. Pearson in his "Principles of Surgery." Chap. I.

A strong solution of alum is perhaps the best gargle that can be used; or a piece of the sulphate of alum may be held in the mouth. Sulphur has also been found useful as an aperient.

Ulceration of the tongue from salivation generally lasts longer than that of the cheeks; the oxymel æruginis may be applied to ulcers on this part, taking care that it is not swallowed. The mouth should be kept as clean as possible, and the little white sloughs which form upon the gums carefully separated.

Some persons have a continual hæmorrhage from the gums during a course of mercury. It has been known to continue for three weeks without any possibility of restraining it. If the gums in such a case are too tender for the use of alum, a decoction of oak bark, with laudanum, may be employed. Exposure to the air should be adopted; and as soon as the bowels will permit, bark, with mineral acids, should be given internally. Should the hæmorrhage be only partial, arising from the separation of a slough, the application of lint, dipped in laudanum, may be sufficient.

It is of great importance to resume the mercury as soon as it can be borne; for if suspended for only a week, the prior quantity must not be reckoned, but it must be again employed without any regard to the quantity used before.

Where there is a great tendency to ptyalism, the patient ought to be freely exposed to the air during the whole course. There are some cases in which it might be thought impossible for a patient to bear a proper course of mercury, but which may be cured by using one drachm of the mercurial ointment every night, and by allowing the patient to go into the open air every day. The cure may take four months.

Whatever may be said by many able men to the contrary, it is certain that exposure to the air does counteract the effects of mercury; and therefore, when such exposure is indispensable on account of its tendency to affect the mouth, a longer time will be necessary for the cure of the disease.

Patients liable to ptyalism should not be allowed to lie long in bed, nor to wrap the head and face in flannel; nor should they be permitted to swallow the saliva, as it is apt to cause sickness, dyspepsia, &c.

In a few instances there has been a recurrence of the ptyalism after mercury has been discontinued several weeks, either from high living or from getting cold.

A ptyalism suddenly suppressed, will sometimes produce pain resembling rheumatism, or affections of the stomach, or even convulsions. In such cases the salivation should be brought back by the free use of mercury, by the warm bath, and by keeping the patient warm. In a case of convulsions from such a cause, an ounce may be rubbed in at a time.

When mercury produces giddiness and a violent pain of the head, a little blood may be taken from the system, unless counter-indicated by great debility.

Mercury sometimes leaves behind it a trembling, not unlike that of palsy; this wears off in time, but if not, a free exposure to the air will be attended with the best effect. Should there be a tendency to diarrhœa large doses of bark will be found most beneficial.

Gonorrhœa.—The term gonorrhœa is applied to an infectious purulent discharge from the urethra in men, and from the secreting surface of the labia, nymphæ, urethra, and vagina in women.

When the discharge is recent, it is called simply gonorrhœa; when of long standing and not infectious, blennorrhœa or gleet. [Gonorrhœa is evidently a most incorrect term for this disease, as from its derivation it signifies a seminal discharge. A more correct term would be "urethritis venerea" for the male; and "vaginitis venerea" for the female.]

In the early stage the lips of the meatus urinarius are red and somewhat tumefied, and the inflammation extends about an inch up the canal. The disease seldom extends beyond the fossa navicularis at first, where a large lacuna is situated. In the beginning the discharge is of a straw colour; and is usually attended with pain in expelling the urine, called "ardor urinæ."

If a drop of the discharge be suffered to remain on white linen, it will appear darker at its circumference than in the centre, and sometimes it has a greenish or brownish hue.

The discharge and ardor urinæ increase till the fourth or fifth day, and generally remain stationary during the next seven days, unless the patient is guilty of some irregularity. Sometimes pain will be felt in the thighs and groins; and delicate persons will complain of pain in the back.

The disease may continue in this state during five or six weeks, or even for as many months, when no remedies have been used to subdue it; on the other hand, there are many instances where the disease has gradually subsided, and finally disappeared, without any means being used at all.

When only one end of the urethra is affected, and the symptoms are mild, it may be called the first species of gonorrhœa; when the whole surface of the canal is involved, it may be termed the second species of gonorrhœa.

In the second species of the disease, the patient, complains of ardent pain above the bulb of the urethra, and of soreness along the whole length of the canal,—*i.e.*, from the bulb to the glans, so that he cannot walk nor cross the legs without causing pain in the perinæum. The discharge is thinner and more profuse than in the first species; and the pain and smarting are not confined to the extremity, but extend all along the canal. The discharge also differs in quality, and it occasions a smarting as it passes down the course of the urethra.

In this species priapism comes on early, attended

with a painful sensation and stricture about the frænum. These symptoms usually take place when in bed. Some persons rarely have the second species without chordee.

Gonorrhœa generally makes its appearance on the third or fourth day after infection. It has been known to take place twelve hours after; and on the other hand it may not appear in some instances till a fortnight or even a month after the application of the matter.

In general the complaint is more severe where the interval is long; this, however, is not an invariable rule; the degree of the disease, and the interval between the infection and its development, very much depend upon the nature of the constitution, and in some measure also upon the particular state in which the patient happened to be at the time of contracting the disease.

Anomalous Appearances of the first and second Species.—Œdema of the prepuce sometimes appears early, especially where the disease is severe, and where the penis is suffered to hang down. The prepuce will have a red and transparent appearance, and in several instances, where there has been considerable hardness and subsequent suppuration in that part of the prepuce attached to the frænum, a small aperture has been found passing through the glans into the urethra.

When the discharge has been suppressed, there has been occasionally observed a particular hardness about the meatus urinarius, attended with a large irregular ulceration of that part, (not chancre,) which, after some time, renders the exit of the urine very difficult to the patient.

Phymosis and paraphymosis are not so frequently the result of gonorrhœa as of chancre; and if they do occur in this disease, they are seldom of so much inconvenience as when produced by the latter. Phymosis is generally occasioned by an œdematous condition of the prepuce, or excoriation of the glans; paraphymosis may be produced also by œdema preputii, when the prepuce is retracted, whilst in that state, beyond the corona glandis.

When gonorrhœa is attended with chordee or priapism, there is increased irritability of the parts, and sometimes inflammation of the frænum and corpus spongiosum; acute pain is referred to the former, and the patient is tormented with frequent contractions or tensions all the night long.

The discharge from the urethra is often thin and tinged with blood, or pure blood may follow the expulsion of the urine. Considerable hæmorrhage has been known to take place, and entirely to remove these distressing symptoms.

Priapism sometimes disappears by the coming on of phlegmon testis, and has not returned on the subsidence of the latter symptom.

The neighbouring absorbent glands, when the inflammatory symptoms have been severe, will inflame and suppurate, especially if the discharge has been suppressed; and even when it ceases, as it sometimes does, without any astringent being used, it might occasion uneasiness about the groins, thighs, and loins. If suppuration of the inguinal glands take place, it will be best to consider it as the result of common inflammation; no ill consequence will follow.

Strangury.—If a patient, who is affected with gonorrhœa, lives irregularly, rides on horseback, or again exposes himself to the exciting causes of the disease, the primary inflammation will very probably be extended to the mucous coat of the bladder.

In such cases soreness is generally felt along the perinæum; and should the bladder be much inflamed, there will be pain in the kidneys and loins, attended with painful and frequent inclination to pass the urine, which is voided in small quantities, either turbid, or mixed with a little blood.

At other times, without any assignable cause, in irritable subjects, and even when the symptoms seem to have gone on well, and no acute pain has been felt at first, the patient will complain of a painful constriction in the region of the bladder, or frequent effort to discharge the urine, without anything coming away, except a small quantity of blood, and there will be great uneasiness felt in the lower part of the rectum, the prostate gland, and neck of the bladder; the pulse will be quick, and there will be great inquietude and distressing micturition.

The symptoms coming on, as they sometimes do, unexpectedly, cannot be prevented, and they make the character of gonorrhœa, both to the patient and surgeon, very vexatious.

Suppuration of the Perinæum is an affection to which some persons are subject in almost every attack of gonorrhœa. Suppression of the discharge takes place in the early stage of the disease, and is followed by violent pain in voiding the urine; the perinæum becomes hard and painful, and suppuration takes place probably about the eighth or tenth day.

Nothing has been found to relieve the severe torture which the patient suffers till the abscess bursts, when he finds immediate ease, and gradually recovers. At this time the discharge from the urethra generally returns, but not always, and it occasionally happens that a sinus is left which communicates with the urethra.

(*To be continued.*)

OBSERVATIONS ON THE EMPLOYMENT OF THE ALCOHOLIC EXTRACT OF NUX VOMICA.

By Edmund Boult, Esq., F.R.C.S.E., Assistant Surgeon to the Bath Eye Infirmary.

Strychnos Nux Vomica (included by Lindley among the Apocynaceae,) has held a place in the Materia Medica since the time of the early Arabian physicians.

It has been exhibited in many forms, but latterly its alkaloid, (strychnine,) has been chiefly employed in this country, and this is the only preparation of the drug given in the "London Pharmacopœia." It cannot be doubted that the most active principles of the medicine are contained in the alkaloid, but from its highly poisonous character, its great activity and liability to adulteration, it is not surprising that many practitioners object to employing it. The pharmacopœias of Edinburgh and Dublin give forms for the preparation of a tincture and spirituous extract of the nux vomica, which are not open to the same objections. The action of this virulent poison has been supposed to be exerted primarily upon the spinal system of nerves, and specially upon the medulla oblongata, as manifested by muscular twitchings, which may be augmented to tetanic spasms; hence its employment in some forms of paralysis. Its effects upon the brain are said, if they exist at all, to be only secondary. I think it highly probable that it exerts a very powerful tonic influence over the ganglionic system, and thus in minute doses it has been found useful in some cases of active dyspepsia, pyrosis, dysentery, and the vomiting of pregnancy.

Some time during the last year I observed in one of the medical periodicals, a recommendation (by a physician whose name I regret I am unable to remember or to verify,) of the extract of nux vomica in habitual costiveness. It was asserted, that if the medicine be continued for some time, the muscular fibres of the intestine respond to the stimulus, and the bowels gradually overcome their accustomed sluggishness. I was induced to make trial of this plan, and was disappointed with the result. I gave half a grain of the alcoholic extract every night at bed-time, to several patients of a costive habit, without any perceptible effect; I afterwards gave the same dose thrice a-day, and found that the bowels responded *very slightly*.

I was then led to add the same quantity of the extract (half a grain,) to a pill containing aloes, rhubarb, and scammony, and was surprised at the result. I found that this drug has the power of increasing very sensibly the activity of purgative medicines. I ascertained that an aperient scarcely sufficient by itself to produce a single evacuation, when combined with this extract, caused active purgation. The dose must be varied according to the patient's idiosyncracy, but, generally speaking, a pill, containing three quarters of a grain of Barbadoes aloes, three quarters of a grain of the extract of rhubarb, and half a grain of the extract of nux vomica, (Pharmacopœia, Edinensis,) if taken at bed-time, will produce one, or, perhaps, two, full evacuations the following morning. The addition of a single grain of calomel to this pill will cause two or three *bilious* motions, thus shewing that the drug possesses not only the property of stimulating the muscular fibres of the bowel, but also the power of increasing the activity of medicines that affect the secretions.

Dr. Christison says, (*vide* "Dispensatory,") speaking of strychnine, that "it is not a cumulative poison, like mercury or digitalis; on the other hand, its activity does not diminish, like that of opium, under the influence of habit." The first of these assertions may be questioned; the second would appear to be true. I have prescribed the pills already mentioned nightly for months together, and at the end of the time the effect has been produced as certainly as at first, and no bad consequences have arisen, no disposition to hæmorrhoids has been set up, and all tendency to cumulation has been carried off with the evacuations; they are indeed remarkably comfortable in their mode of operation, and so far from injuring the tone of the digestive apparatus, I think it will be found that when the medicine is discontinued, the disposition to costiveness will be found lessened. It would be interesting to ascertain how far the exhibition of nux vomica can modify the effect of medicines of a different kind; I have occasionally employed it in combination with quinine, but I am not prepared to say what extent of modification or increased activity has resulted.

There is nothing novel in the combination of tonics with purgatives, which is especially indicated for children of atonic habits. By this means the operation of the purgative is rendered more active, and more persistent if the medicine be continued. Mastich we know has the property of increasing the powers of aloes, when given in combination; this is said by Pereira and others to be the result of a more minute subdivision of the aloetic particles, which the mastich favours; but I have seen no combination produce anything like those marked effects which have been mentioned as resulting from the employment of the nux vomica.

There is an observation to be made with regard to the employment of this medicine, in order to prevent disappointment to those using it. It is essential that the extract should be *good*. Alcoholic extracts are troublesome and expensive to make: this preparation is particularly so, and consequently the common article of commerce is not always to be depended upon.*

I place these observations before the profession, believing that an aperient (such as I have found in this combination,) which will produce a comfortable and persistent effect, may prove a desideratum for many who are troubled with habitual costiveness.

Since the above remarks were written, I have observed that Dr. Copland, (Dict. Pract. Med. Art. "Constipation.") recommends the employment of the spirituous extract of nux vomica, or strychnine, in

* That which I have employed has been prepared for me by Mr. Tyler, chemist, of this city, and has never failed to produce the desired effect.

combination with purgatives, in cases of constipation, depending upon atony of the muscular fibres of the large intestines, or want of propelling power at the upper part of the rectum; but as he makes no allusion to the *very small quantity of the purgative* required, nor to the influence of the medicine upon the other organs supplied by the sympathetic system, &c., I do not think I need withhold the forgoing observations.

Bath, April 26, 1848.

CASES FROM PRIVATE PRACTICE.*

By John Richard Wardell, M.D., Edin.;

Late President of the Royal Physical and Hunterian Medical Societies, Assistant Pathologist in the Royal Infirmary, Edinburgh, &c. &c.

Case VII.

Fits during Labour.

Ann Shaffell, aged 24, single, low stature, broad-set frame, and muscular system fully developed, hair dark, nervo-phlegmatic temperament, looks healthy.

January 18th, 1848. At three o'clock this morning was awakened from her sleep by incipient pains of labour, which continued at intervals, and increased in power up to eleven o'clock, the time at which I first saw her. On making an examination, the head was tolerably low down in the pelvis, and the os uteri was dilated to not more than the size of a shilling-piece; parts quite cool, and well lubricated. Patient stated the waters had broken early in the morning; this, however, was manifestly incorrect, as the membranes could be distinctly felt entire. Deeming it of little utility to wait, as it was very probable her delivery would not soon take place, as judged from the extent of dilatation, and the degree of force and frequency of the pains, I left her, with strict injunctions to be summoned if any sudden change supervened. At half-past twelve I was sent for in great haste, it being reported that the pains had now become very frequent and much stronger. On my arrival the os uteri was almost entirely dilated, pains, however, now abated, and for some time she remained in *statu quo*. She had three or four pains, which were not very severe, after I had entered the room, and to all appearance everything was progressing in the most satisfactory manner, and she was partially reclined on the bed; at this moment my attention was quickly directed to the patient, by the nurse who was standing by her bed side, and who in her alarm shouted "Doctor, she is in a fit." The eyes were everted, the hands firmly clenched, and the entire muscular system in a state of considerable rigidity. There was no foaming at the mouth, little, if any, tossing about of the head on the pillow, no stertor, and the paroxysm was of short duration. Cold was applied to the head, though this did not seem particularly indicated, as the surface generally was not above the normal degree of temperature, nor was the os frontis, but as we frequently, during such paroxysms, observe it. Whilst the fit continued, the countenance was much congested, and assumed a dark rose-red; the eyes were suffused, and seemed fierce and glassy; the pulse slow, and though of small volume, of tolerable strength. I should have bled her, but unfortunately I had forgot my lancet case, and thus some delay was unavoidable, the place being at a short distance out of the town. Considering it desirable that the child should be born as soon as possible, I dispatched a messenger for my friend Mr. Cole, and desired him to bring the short forceps without delay. The head had descended too low down to turn, and the forceps seemed to be the most desirable mode of procedure. Immediately after the fit had subsided, I ordered a sinapism to be placed along the whole course of the spine, also others to the legs and feet, hot bottles were applied to the extremities, and additional coverlets thrown over her, to induce, if possible, more heat on the surface. In less than half an hour Mr. Cole arrived with the instruments, which I at once applied, and the child was readily extracted. She had not had another fit during this interval. The placenta was removed in about eight minutes afterwards, with scarcely any loss of blood. She remained from the time of the fit insensible, and spoke with vehement incoherence. The eyes were wandering, and gave a vacant expression to the countenance, and she constantly stared about as if in bewilderment. Pupils both fully dilated. Child born about a quarter-past one, p.m.

In the first half hour after delivery she had five fits, each characterized by the same phenomena as the one described, but of a milder description. Conceiving that a moderate degree of depletion might, by relieving the general congestion, be of service, although the pulse was slow and small, Mr. Cole agreed to this opinion, and we consequently, with caution, resolved to bleed her into a tea-cup, watching at the same time the effect which it produced on the heart's action. On opening a vein in the arm, not half an ounce could be obtained. The pulse became slower, of less volume, and weaker, its beats not being more than 44 per minute. The skin, in despite of every endeavour, grew colder, and the countenance looked livid and congested. The compound camphor liniment, with the strong liquor of ammonia, was freely rubbed on the chest, and an enema administered, with a drachm each of laudanum, and the compound spirit of ammonia, and an ounce of turpentine, in half a cupful of oatmeal gruel, which was retained. Symptoms of amendment not becoming manifest, it was very properly suggested by Mr. Cole that voltaic electricity should be tried, with a view if possible to rouse the central organs of the nervous system. Mr. Cole, who has long used galvanism as a medicinal agent, and often with marked success, had by him three or four descriptions of apparatus; that of Bichoffners was selected, and readily rendered available. I carefully noticed the pulse, which was now 58, and Mr. Cole then placed one wire behind the neck, the other over the last lumbar vertebra. In ten minutes the pulse rose to 100, and remained at that degree of frequency so long as the electric fluid was employed. She soon expressed herself as being

* Continued from page 96.

"better," and seemed more collected. In a quarter of an hour after the wires were discontinued, the pulse fell to 80, but was of improved strength and volume; the skin generally grew warmer, the looks were more natural, and she now answered questions rationally.

Eight o'clock. (*Vespere.*) No return of fits; surface warm and moist; pulse 64, of good volume and strength. Ordered a little gruel, and hot bottles to the feet.

19th. (*Mane.*) Slept but little during the night, and until three o'clock was loquacious and wandering; had no fit since yesterday afternoon; pulse 66, of better strength; is quite sensible, and expresses herself as improved. Upon enquiry states that she has had considerable headaches during the first two months of her pregnancy; never had any fits before, at any period of her life; always enjoyed good health; urine, up to the time of her delivery, had always appeared natural, and voided in proper quantity; bowels have often been confined during the last two or three months, and says that last week were a good deal constipated; yesterday morning diarrhœa came on, and she was purged three or four times; says she had headache yesterday morning, (chiefly over os frontis,) and that at times she fancied every thing turned round. Does not remember her delivery. Urine voided normally, of specific gravity 1.010, does not coagulate by heat; nitric acid produces no effect; litmus paper is unaltered.

Half-past one p.m. Summoned in great haste, it being reported she has had in quick succession three fits, which were pretty similar to those yesterday. No foaming at the mouth. On my arrival was sensible; countenance red and flushed; skin hot; pulse of better volume and strength; tongue rather dry; eyes a good deal injected; head hot; some lachrymation; pupils normal.

Venesectio ad oz. xi., (which was carried so far as to produce a slight impression upon the pulse.) R. Calomelanos, gr. iv.; Pulv. Opii, gr. iss.; Extr. Hyoscymi, gr. iv. Misce. Fiat pil. ij. statim sumendæ. Empl. Lyttæ nuchæ. A bladder of ice to be applied to the head.

Eight o'clock, (*vespere.*) No return of fits. Since she took the pills she has had a tranquil and continuous sleep; says her head feels "comfortable" since the application of the ice; pulse 76, full and soft; skin moist; tongue not at all dry, and tolerably clean. Countenance natural, and expresses herself as much better.

January 20th. (*Mane.*) In every respect favourable. No return of fits.

Vespere. Is still going on favourably. Bowels not moved.

R. Sol. Morph. Mur., gtt. x.; Ol. Ricini, dr. iv.; Aquæ Menth. Pip., dr. iv. Sit haustus statim sumendus.

January 21st. Progresses favourably.

Vespere. After having been up at stool she had a slight fit. Nurse did not send at the time but applied a bladder of ice, and she is now comfortable; nor does she complain of pain in the head. Bowels regular; pulse natural; tongue clean.

22nd. Favourable.

25th. Up to this date in every respect went on well. Reported that about ten o'clock this morning had a return of fits; pulse most particularly full and of not more than natural frequency. Complains of considerable pain in the head; bowels regular; skin warm.

Venesectio ad deliquium animi. R. Pulv. Opii, gr. ij.; Pulv. Sodæ Carb., dr. ss. Sit pulvis statim sumendus.

26th. Had another fit last night, which from the description, was of an hysterical character; no foaming, but some convulsive agitation. Blood drawn, natural. Bowels open; pulse of good volume and strength; had a tolerable night; countenance clear and natural; complains of some tenderness over the inferior part of the abdomen; no lochial discharge.

27th. Improves.

From this time the case progresssed in the most satisfactory manner, and in the course of a few days was pronounced convalescent.

27, Acacia Road, Regent's Park, London.

(To be continued.)

CLINICAL NOTES FROM PRIVATE PRACTICE.*

By W. H. Ranking, M.D., (Cantab.,) Norwich.

3. *Double Pneumonia; Hepatization of the Posterior Portions of the Lower and Middle Lobes of both Lungs: Recovery.*

A young gentleman, aged 17, of delicate frame, subject in infancy and childhood to repeated attacks of inflammatory croup, after exposure to cold was attacked March 22nd with symptoms which were considered to indicate a common "bilious attack." It appears that he had some cough from the first, but this symptom was not so severe as to cause any anxiety on the part of his medical attendant until the 27th, when a sudden aggravation of the pulmonary symptoms induced him to seek my co-operation.

When seen by me on the morning of the 28th, the patient was in the following condition:—Decubitus on the back, raised by pillows; countenance sunken, pale, and anxious; alæ nasi in rapid motion; whole surface bathed in perspiration; respiration 60 in the minute, abrupt and superficial; pulse 130 to 140, feeble; cough slight; expectoration scanty, tenacious, and rusty. On raising him into a sitting posture, it was found that all the auxiliary muscles of respiration were in full play, and it was evident from the short and rapid breathing that a small portion only of the lungs was pervious to air.

Physical signs.—Dulness on percussion of the posterior portions of both lungs, extending from an inch above the angles of the scapula on the left side, and about half an inch on the right; above these points, and over the anterior regions of the chest, the stroke-sound was normal, or nearly so; over the entire space indicated by dulness on percussion, the vesicular murmur was extinct, and in its place loud bronchial or tubular breathing was heard, the expiratory "whiff" being peculiarly well marked. These signs were developed in their greatest intensity on the left side.

* Continued from page 233.

In the upper lobes, posteriorly and in front, the respiration was puerile, but no crepitus could be discovered by the most attentive examination. The lower ribs behind were motionless.

The above combination of physical signs, pointing out distinctly the existence of double pneumonia in the stage of hepatization, treatment to the best of my judgment, suitable to the emergency, was at once adopted. Six leeches were ordered between the angles of the scapulæ as the only depletory measure admissible, and these were to be followed by a blister. The subjoined pill was also exhibited every two hours:—

R. Hydr. Chlorid., gr. ij.; Ant. Potass. Tart., gr. $\frac{1}{8}$; Pulv. Opii, gr. $\frac{1}{4}$. Fiat Pilula. And eight grains of sesqui-carbonate of ammonia were given every four hours, in Decoct. Senekæ. Beef tea *ad libitum*.

29th. The leeches had bled well, and the patient expressed himself as relieved at first by them, but at the time of our visit he was apparently all but asphyxiated by the sudden accumulation of bronchial secretions, which he was unable to expectorate. Suffocation appearing imminent from this cause, he was raised into the semi-erect posture, and brandy and water administered several times during the day.

30th. Has expectorated a considerable quantity of frothy phlegm, under the stimulus of the brandy, and the immediate danger of suffocation has passed. The mucous rhonchi have also subsided as suddenly as they appeared.

For the next two days there was no very obvious change, but it was evident that the patient did not lose ground, a matter, under the circumtsances, sufficiently encouraging. Pergat.

April 2nd. General aspect improved; respiration sank to 40, and the pulse to 100; skin cool; tubular breathing less distinct, and vesicular breathing beginning to appear, especially on the right side. *No "crepitus redux" heard*, though carefully listened for. As the bowels had been several times purged, and the motions were green, the calomel was replaced by mercurial dressing to the blister, and he had Mist. Cretæ.

4th. Expresses himself as considerably better; scarcely any cough, and expectoration scanty, but less tenacious, containing a small quantity of pus, and occasionally streaked with blood; gums becoming tender; purging suspended. Both lungs "clearing up;" tubular respiration almost gone on the right side; *still no crepitus*.

5th. Mercurial fœtor well pronounced. The blister to be dressed less frequently. Ordered Pulv. Ipecac., gr. j; Extr. Conii., gr. iv., in pill, every six hours. To continue the mixture.

7th. Pulse 90; respiratory murmur heard fully to the base of the right lung; the left less permeable to air.

12th. Has continued steadily to improve; there has been but little cough or expectoration, but the respirations and pulse have gradually come down to the natural standard. Sits up and takes food with appetite. On examination of the chest, the left side is observed to be flatter than the right, and measures less by nearly an inch; it has a less extent of motion in breathing, but air may be heard to penetrate to the base, by causing the patient to take forced inspirations. Ordered Potass. Iodidi, scr. j.; Vin. Ferri, oz. j.; Infus. Gent., oz. vj. Sumat cochl. magn. ter in die.

From this period no regular reports have been taken, but occasional examination has satisfied me that the left lung is gradually recovering itself, and the side expanding in proportion. He has now returned to his usual food and habits.

The above case offers instructive evidence of what energetic medical treatment is able to accomplish, under apparently the most hopeless circumstances, and affords as triumphant an answer as could well be wished to those who would depreciate the efficacy of medicine, in order to magnify the restorative powers of unassisted nature. At the time of my first seeing the patient his vital energies were so much sunk, and the extent of lung rendered useless for the purposes of respiration so great, that I did not entertain the smallest hope of saving him, but, on the contrary, his death appeared all but inevitable—certain, if he remained many hours longer unrelieved. Pneumonia advanced to the stage of hepatization, and occupying a large portion of even *one* lung, is a disease of very considerable danger, and medical efforts are often baffled, although the patient possesses one sound lung for the maintenance of respiration. Here the major portion of both organs was rendered impermeable by air, and recovery must be looked upon as a rare and fortunate event. Andral states that he has never known a patient recover from pneumonia, whose respirations reached fifty in the minute. In the present instance this number was exceeded, and they remained as high as forty for a space of two days.

Two points especially worthy of notice are the trifling amount of cough and expectoration, and the restoration of the lungs, without the re-appearance of the "crepitous rale." It is the not uncommon absence or trifling amount of cough, which causes pneumonia to be so often overlooked in its early stage by those who are not conversant with the practice of auscultation. An instance has occurred to me within the past year of one lung becoming almost universally solidified from pneumonia, which the medical attendant, an elderly practitioner, quite unacquanted with auscultation, and occupied by a co-existing jaundice, had entirely failed to recognize; nor could I convince him of the fact, *because there had been but little pain and cough* in the earlier period of the attack. I saved this lady's life by at once commencing a vigorous mercurial treatment, but to this day I have reason to know the gentleman in question considers that the solidified lung was the offspring of my imagination.

The second point to be noticed, (the restoration of the hepatized lung without the reproduction of "crepitus,") is one of particular interest. From the time of Laennec till now it has been known, that when a portion of lung which has been solidified by inflammation begins to be restored, the crepitous rale which had disappeared as bronchial breathing becomes developed, again re-appears as the "crepitus redux."

That this is the ordinary course of events is beyond dispute, and is alluded to by Watson, Williams, and, in fact, by every recent writer and lecturer on diseases of the chest. It may, therefore, be readily imagined, that I was not a little surprised to find that, though there was indisputable proof of amendment in the condition of the lungs of our patient, I yet could not on the most minute and repeated examination discover any "crepitus redux." The character of the breath-sound passed at once from the bronchial to the vesicular, the latter gradually gaining upon, and eventually displacing, the latter. I could not at the time account for this, and was content to note it down as a *fact*, that "crepitus redux" is not an invariable accompaniment of the resolution of pneumonia; when, upon turning to that admirable example of bed-side teaching, Graves' "Clinical Medicine," I found the same fact had been observed by its author, and under precisely the same circumstances as were offered in the present case—viz., recovery, with trifling cough, and little or no expectoration. Dr. Graves remarks, that in ordinary cases resolution of pneumonia takes place by increased secretion, together with interstitial absorption, but the latter alone is sufficient in certain instances. When such is the case, and no secretion takes place into the bronchial ramifications, there can be no "crepitus redux."

This case offers still another feature of interest, in the sudden occurrence of imminent suffocation from effusion into the larger bronchial tubes on the 29th. This effusion was evidently asthenic, resembling that which occurs towards the close of many other diseases. It might not have been of so much importance under some conditions of disease, but here it was a most formidable complication, obstructing what little portion of pulmonary tissue had been spared by the original malady. It was promptly met by the free exhibition of brandy, a few doses of which enabled the patient to discharge a quantity of frothy mucus. The urgent debility being thus obviated, the symptom did not re-appear.

The treatment was conducted on general principles. Depletion to any extent was inadmissable, and it is questionable if free blood-letting is of use after hepatization has taken place, even if the patient's strength would tolerate it. All that is necessary in this stage, is by removing a small quantity of blood, to induce something like a balance between the bulk of the circulating fluid, and the diminished capacity of the lungs. I regretted even the application of a few leeches, in the present instance, and am not sure that they were not the cause of the sudden bronchial effusion above mentioned. It will be seen that mercury was looked to as the sheet anchor. Such I regard it to be in the stage of hepatization. The time is then gone by when good is to be expected from the use of large doses of antimony. The air-cells are clogged by fibrinous deposit; and the best absorbent of lymph, whether in the pulmonary tissue or between the layers of the cornea, is mercury. The iodide of potassium also did good service in completing the resolution of the obstructed lung.

PROVINCIAL
Medical & Surgical Journal.

WEDNESDAY, MAY 17, 1848.

We insert this week a letter from a Midland Counties' surgeon, in reference to the recent actions against the Midland Railway Company, for remuneration for professional services rendered, in the case of a poor man, who had suffered a severe accident on the railway. A report of these trials will be found in the *Provincial Journal* of April 19th, together with some brief comments, which we deemed it right to append. The author of the letter thinks, that in these comments, our "zeal for the interests of the profession, has to a certain extent outrun our discretion." Individually we might be well content to underlie this imputation, seeing that we are not alone in the views which we have taken of the conduct of the Company on this occasion,—that the sentiments which we ventured to express were, "to a certain extent," partaken in by the counsel, the Court, and the jury, and would seem to be justified even by the defendants themselves. The counsel, we are informed, "remarked rather strongly on what he characterized as the shabby, mean, and most ungenerous nature of the Company's procedure, in refusing to liquidate the claim. The Judge "suggested that as it was contended for the Company that no servant of theirs had authority to order medical attendance in cases of accident (the plea set up on the part of the Company,) they ought to make it publicly known. The jury, under the direction of the Judge, returned a verdict for the plaintiffs, and even the defendants "did not dispute the justice of the charge, but merely pleaded that they were not indebted," on the ground that their officer had no authority to make a contract with the medical men.

Seeing therefore that such is the recorded opinion of the parties concerned, and that the presiding Judge held the responsibility of the officers of the Company, we do not think that either in any of the observations which we made, or in the conclusion on the conduct of the Company at which we arrived, we can with any justice, be said to have allowed "zeal to outrun discretion;" and further we are still of opinion, notwithstanding the observations of the author of the letter, that the attempt of the

Company to deprive the surgeons (the justice of whose charge was not disputed,) of the remuneration to which they were entitled, was "pitiful in the extreme."

Still, as we have intimated, we should not under the circumstances have been disposed to notice the imputation brought against ourselves; there is, however, an important principle concerned, established by the result of the trials, which it is most desirable should be cleared from any fallacy or misconception in which the observations of the author of the letter might tend to involve it—the liability of railway companies to make all possible reparation for the injuries committed by them.

The author of the letter would seem to be of opinion, that the sufferer from the accident, being a person in humble circumstances, was entitled only to such relief as his circumstances might have enabled him to obtain for himself; that the charges of the surgeons in attendance should have been made in accordance therewith; and that the extra-assistance of Mr. Sands Cox was uncalled for. This it will be observed is not the ground of defence set up by the Company: they disputed not the *justice* of the charge, but forgetting, or endeavouring to shelve, the legal axiom, *qui facit per alium facit per se*, pleaded that they were not liable for contracts made by their own agents. The objection of the author of the letter, then, is not to the liability of the Company, but partly to the amount and quality of the assistance rendered, and partly to the sum charged for such assistance, on the plea of the humble station of the sufferer. Now, for ourselves, we must say that we differ altogether with the writer of the letter on this point, and we will do the Company the justice to think that, were the question put to them, they would at once say, as their agents did say, let every thing possible be done to save the man's life.

With regard to the supposed instance of an innkeeper, acting under orders from a nobleman, to take care of a poor man, accidentally injured by one of his servants, we are not aware that it would be either necessary for, or advantageous to, a poor man so circumstanced, that he should be placed in "the best apartment" in the house, "at two or three guineas a day;" nor is it in accordance with our experience, that "turtle and champaign" is the form of diet best suited to a person under the circumstances supposed. But the innkeeper would have an undoubted right, and it would indeed be his duty, to place the patient in one of the most airy and comfortable rooms in the house, and to supply him with such nourishing food and good sound wine, or other stimulus, as the circumstances of the case might call for, and be entitled also to make his full and customary charge for the same.

We are not now considering whether it was necessary that so many surgeons should have been in attendance, but we can readily conceive, that in so severe an accident as the crushing of both thighs, attended with great hæmorrhage, and rendering amputation inevitable, involving also a probable charge of manslaughter should the patient die, few surgeons would be found to act singly on their own responsibility. On the contrary, most surgeons would be glad to summon any of their brethren to their immediate aid, and in the event of an important operation being required under circumstances of such moment and danger, would be desirous further of obtaining the most eminent assistance within reach. And surely such being the case, the Company being well able to bear the expense, the claim of the surgeons to a remuneration for the skill, and care, and attention requisite for its management throughout, and for the responsibility entailed upon them, is just and eqitable.

Review.

A Treatise on Diet and Regimen. By WILLIAM HENRY ROBERTSON, M.D., Physician to the Buxton Bath Charity. Fourth edition, re-written, and much enlarged, in Two Volumes. Volume I. London: post 8vo., pp. 355.

It would be difficult to over-estimate the importance of the great hygienic subjects comprehended in the title of the work before us. Every advance in chemical investigation,—every development of statistical facts, shows, more and more clearly, how much more powerfully disease and mortality are to be antagonised by the means of prevention, than those of cure. When we think of the large proportion of the deaths in this country that is made up of epidemic diseases, and that a more efficient ventilation, and a better drainage and sewerage, might well nigh sweep away such diseases from the causes of death, widowhood, and orphanage;—when we think of the prevalence of pulmonary disease, and think how a large proportion of these cases is fairly referable to deficient ventilation, and a neglect of the great organic laws, on the part of those attacked;—when we regard scrofula in all its forms, as being but the accumulated result of inattention to the great means of hygiene—the consequence

of disobedience to the organic laws,—we feel that the subjects of diet and regimen are at least as important, at least as deserving of patient study and anxious investigation, as the pathology and treatment of disease.

In the present edition of the work before us, Dr. Robertson has brought down the several subjects to the present time, to the advanced state of chemical and statistical science, and he has availed himself of the researches of Dr. Prout, Professor Liebig, Dr. William Gregory, &c. &c., adding thereto a digest of the results of parliamentary inquiries into the several great questions embraced in his work. The first volume, now under review, opens with a statement of the several causes and classes of disease, and a demonstration of the awful ravages of the removable causes of disease, urging these as great facts, which demand the fullest attention,—an attention which can only spring from general enlightenment of the people, and the co-operation and supervision of an active and well informed executive. Our author justly urges, that an indirect result of such increased knowledge of the great hygienic laws would be a death-blow to quackery in all its forms. The second chapter or section, which occupies the remainder of the first volume, embraces the vast subject of dietetics. The processes of digestion are considered briefly but analytically, and the vital character of all the assimilating functions, overruling and determining the chemical action, and its results, is prominently advanced. The several articles of food in ordinary use are noticed *seriatim*,—their chemical constitution, relations, and dependencies,—their relative digestibility,—their effects on the nutrition of the system, and on the respiratory wants of the economy, are duly dealt with, and it would be difficult to look for an article of food that is not particularized; at the same time, the relative effects of animal and vegetable food,—of azotized and of non-azotized articles of diet,—of the oily, the saccharine, the amylaceous, and the albuminous foods, and of the more aqueous aliments, &c., are stated. The important question of the use and abuse of alcoholic compounds is examined on its intrinsic merits; and the tee-total quackery on the one hand, and the indiscriminate use of any of the products of the vinous fermentation on the other, are equally avoided.

The followers of hydropathy might possibly read the subjoined passage, as to the emulging effects of water, with some benefit:—

"As to the ultimate action of water on the system,—its effect as a solvent for the effete matters, and a direct means of their elimination,—the influence of the great solvent may be made useful in many disordered conditions of the body, and on the other hand, may be carried much too far, and with injurious consequences to the system. It seems to be a simple enough fact, that however pure may be the state in which water is taken into the system, it is never pure when discharged from it, but always carries off, in solution, saline and azotized matters, and is, to the same degree, an emulging and expending agent. This may be most useful in maintaining health, in warding off disease, or in correcting or removing morbid action. It may promote needful secretion; it may carry off redundant matters; it may relieve local irritation; it may equalize the general circulation, or remove the slighter degrees of congestion; and act beneficially upon the plethoric, the sluggish, or the excited conditions of the system, which may or may not be sufficient in degree to amount to disease. The good effects of water, as a diluent and emulgent, in the human body, whether in health or disease, can hardly be exaggerated in importance. But, in the same degree, it is possible to make too much use of so energetic an agent;—to the same degree, it is possible to make it a means of inducing debility, whether local or general, and an unwise means of expending the powers of the system. Water is by no means a weak and unimportant agent in the animal economy, and is as capable as most other powerful agents, of subserving the well-being, or of deranging the tone and healthiness, of the system. It has been, of late years,—thanks to an extension of one of the forms of modern quackery to the habits of the people!—too much the custom to drink water more largely than the system requires its diluent and emulgent action, in the delusive hope of its acting, in some mysterious way, as a tonic and remedial agent. However taken, when used in larger quantity than the wants of the system imperatively require, water must always act as an emulgent, and, to the same extent, as an expending and debilitating agent,—and should by so much be made use of cautiously in any excessive degree, and only according to the evident requirements of the system, whether it be healthy or diseased, and with a view to, and due consideration of, its emulgent effects."

Dr. Robertson continues his dietetic section with an elaborate inquiry into the quantity of food required for the maintenance of health and strength under different circumstances, illustrating and founding his observations and deductions on the dietaries of hospitals, gaols, the departments of the public service, &c., &c., which are given *seriatim*. We have reason to know that these several dietaries have been obtained at the expense of considerable trouble, and that this department of Dr. Robertson's work has been ministered to by many medical friends. "It seems from the tabular estimate derived from the different dietaries quoted, that from thirteen to twenty ounces of dry nutriment, and from four to six ounces of azotized aliment, is a needful daily ration for people who have to undergo regular and active exertion; and that less than the lowest of these quotations would be an unjustifiable allowance to adults in health, who are called upon to work. Such an estimate is easily made, and should be considered a necessary step previous to the adoption of any plan of diet for the inmates of public institutions, or the dependants on public charity." Dr. Robertson is no advocate for a low dietary,—for such an amount

of sustenance as will barely serve to support existence. He claims (and most justly,) for all classes, whether the inmates of our union-houses or the felons in our gaols, the pauperized or the criminal, such a scale of diet as will do more than barely maintain the expenditure of the system, on the ground of policy as well as that of justice and of humanity, for the sake of the common-weal as well as for that of the individual advantage; lest, as perhaps always happens under such circumstances of defective nutrition, fever step in, with its gigantic powers, and destroying with its pestilential breath the victims of the so-called economy, extend its ravages to the classes of people above and around them, and multiply the consequences of the sickness and the deaths by the pauperizing influences of widowhood and orphanage.

In concluding this first volume, Dr. Robertson says,—"The question as to the feeding of the indigent, the sick, the aged, and the labourer, brings the subject of dietaries within the direct influence of the legislature, and renders its details and facts of inappreciable value. There can be no question that, by dietaries which have been unequal to the wants of the system, or have not been adapted in character to the attendant circumstances of life, disease in its worst and most fatal forms, has been many times induced, in places of punishment, of well-intentioned charity, of manufacture, and of education; or that, without constant recurrence to the principles of dietetics, such occurrences may be reasonably expected to occur again. It is only a knowledge of the ordinary and the extraordinary expenditure of the system, of the varying expenditure dependent on age, season, climate, toil, &c., and of the nutrimentary qualities of different kinds of food, that can afford a secure basis for the establishment of useful dietaries, and adjust their modifications to suit the various requirements of the economy under different circumstances."

We shall resume our notice of Dr. Robertson's work when we are in possession of the second volume, which is promised in the course of a few weeks. In the mean time we have great pleasure in recommending this edition to general attention, as giving a rational view of many questions of vital interest and importance to the community, and to the medical practitioner especially, as enabling him to obtain ready access to much valuable information, both on subjects connected with public health, and on the dietetic management of the dyspeptic.

INQUIRY INTO THE MEDICINAL ACTION OF ARSENIC.

NOTICE TO MEMBERS.

Mr. Hunt, of Herne Bay, being anxious to prepare for the annual meeting of the Association a digest of the experience of its members on the medicinal action of arsenic, earnestly requests that those members who have not yet favoured him with replies to the questions printed in the Journal for December 1st, 1847, will evince their zeal for medical science by forwarding their reports to him before the end of the present month, (May.) Mr. Hunt begs to acknowledge the receipt of very numerons communications, containing records of many thousand cases, embodying facts and observations which, when presented in a tabular form, will be read with great interest. To save the trouble of reference, we reprint the questions alluded to, and trust that those members who are in possession of valuable facts will not fail to respond promptly.

Questions.

1. In how many cases have you had an opportunity of watching the internal administration of arsenic in medicinal doses?

2. Did you ever see a case in which arsenic so administered, proved fatal; and if so, what are the proofs that the death of the patient was caused by arsenic; and what dose was administered, and how often?

3. Have you any proofs, that under your own observation, arsenic has ever, in medicinal doses, proved seriously or permanently detrimental to the health? If so, state the symptoms, and mention the facts which prove that arsenic was the injurious agent.

4. Did you ever see it administered without producing any apparent effect on the system, and if so, in what dose, and how long was it persisted in?

5. In what disease or diseases have you seen arsenic useful, and to what extent? What proofs can you give of its efficiency?

6. Irrespective of its therapeutic efficacy, what effects have you observed to result from the medicinal use of arsenic? And what proofs can you adduce that these effects were real—not imaginary?

7. Is there any one symptom (or more) which you have found *invariably* resulting from its exhibition; and what symptom or symptoms?

8. Have you noticed much variableness in its action in different cases, or the contrary? Have you observed its effects modified by age, sex, or idiosyncrasy; and to what extent?

9. State generally the *conditions* which have guided you in the administration of arsenic; what you have regarded as the sign or signs of an overdose; and what the circumstances are, which in your experience have seemed to contra-indicate its use.

10. State particularly what preparation you have used; what doses; whether administered on a full stomach or fasting; whether in increasing, decreasing, or uniform doses; whether alone, or in combination; whether in hospital or private practice.

11. What proof can you offer that the preparation you have used was pure?

12. Have you used arsenic externally? In how many cases, and in what diseases; and with what effect, local and constitutional?

13. Can you refer to any valuable papers or treatises on the medicinal use of arsenic, which may assist in the prosecution of this enquiry?

14. Can you mention any facts of interest occurring under your own eye, connected with the subject, not referred to in these questions?

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I forward to you a collection of facts, extracted from the depositions made at the inquests, held before the coroner of Manchester. I beg publicly to acknowledge my sense of Mr. Chapman's courtesy and kindness, in permitting me to go through the depositions, and make such extracts as seemed likely to promote the object I have in view.

As it requires a good deal of labour to go through the depositions, I send you a rather full analysis of them. I think they will be of considerable value to me in the preparation of the report for the annual meeting, and I hope that some philanthropist may hereafter be led to refer to your pages for the appalling facts embodied in these depositions. The sacrifice of life by burns and scalds is very great.

I have retained the phraseology of the depositions; to have departed from it would have been to endanger the accuracy of the digest.

I have the honour to be, Sir,

Your very obedient servant.

SAMUEL CROMPTON.

Manchester, May 6, 1848.

Digest of Depositions before the Coroner of Manchester.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death.	Parts which were burnt.	How the accident occurred.	Remarks.
1	M.	2 yrs.	1839 Mch. 30	17 days	Left arm, fore-arm, shoulder. Left breast and left cheek slightly	Clothes caught fire during the mother's absence	Under a quack, who deposed that his remedy was elder ointment and *white-lead*, made into a plaster. Linseed oil and lime-water in the first instance.
2	F.	22 yrs.	April 17	8 days	All over the body: the *back* chiefly	Sitting upon the kitchen fender with her back to the fire. A cinder supposed to have fallen upon her dress. Her fellow-servant tried to extinguish the flames. The deceased ran out of the kitchen, and into different rooms, enveloped in flames	Taken to the Royal Infirmary. Linseed oil and lime-water having previously been applied to the burnt parts.
3	F.	12 yrs.	Mch. 26	31 days	Breast, arms, & part of neck	Whilst putting something into a pan upon the fire, she turned round to speak to a female, when her pinafore caught fire	Was carried to the Infirmary immediately.
4	F.	9 yrs.	April 28	6½ hrs.	Thighs, stomach, arms, & a little on the back	During the absence of the mother, her clothing caught fire, but *how*, it does not appear	Taken to the Infirmary.
5	M.	4 yrs.	April 27	—	Dreadfully burnt over all the body.	Pinafore caught fire in making a bonfire	Taken to the Infirmary
6	M.	2⅔ yrs.	April 14	15 days	Right arm breast and chin	Was passing a table on which was a dish, containing two or three quarts of soup, which he upset upon himself	Taken to the Infirmary.
7	M.	8 yrs.	April 23	21 days	All the body, from the chin to the knees.	Fell head-foremost into a tub of hot size. When he was undressed the skin came off his body	Taken to the Infirmary.
8	F.	Adult	——	——	——	Unknown woman, who was found burnt to death near a brickkiln. It is supposed that she had been sleeping there, and that her clothes caught fire	——
9	M.	4 yrs.	June 11	5 hours.	Much burnt all over both arms, chest, belly, back and face	In mother's absence supposed to have been taking a potato out of the pan upon the fire	——
10	F.	3 yrs.	July 15	2 days	Legs, arms, neck and throat, severely	Fell into a canful of boiling water	Taken to the Infirmary, after the application of linseed oil and lime-water.
11	M.	34 yrs.	Aug. 22	11 days	Chest, belly, and left arm	A farrier. Fell into the fire of the forge when in a fit	Taken to the Infirmary.
12	F.	79 yrs.	——	——	Face, breast, right arm, & shoulder	Was reaching over a table, upon which there was a lighted candle, when her clothes took fire	Taken to the Infirmary.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death.	Parts which were burnt.	How the Accident occurred.	Remarks.
13	F.	5½ yrs.	Sept. 23	11 hours	———	Child's clothing caught fire in the absence of the mother. Supposed to have been playing near to the fire	Taken to the Infirmary.
14	F.	13 yrs.	Oct. 9	5½ hrs.	All over her body, both legs down to the ankles	Sitting by the fire, asleep, when a cinder fell upon her frock. No mother.	———
15	M.	1 year	Oct. 6	4 days	Right arm, right side of head	Left in the house with a little girl, eight years old. He fell under the grate and hot ashes fell upon him and set fire to his clothes	No regular medical advice. Was dressed by a neighbour with linseed oil and lime-water.
16	F.	4 yrs.	Oct. 18	3½ hrs.	Both thighs, the belly, and the arms	Went down stairs in her night clothes whilst her mother was in bed, and is supposed to have gone too close to the fire	Taken to the Infirmary.
17	F.	yrs.	Oct. 9	12 days	Left breast severely scalded.	Pulled over a cupful of hot tea from the table into her breast	Linseed oil & lime-water. Afterwards under Mrs. Thorpe. No regular practitioner called in.
18	F.	3 yrs.	——	Oct. 30	Right arm, face and head	Clothes caught fire: no one in the room with her	Linseed oil & lime-water.
19	M.	2½ yrs.	Oct. 30	24 hrs.	Both arms, chin, right ear, and right thigh	Mother "out" washing. Clothes caught fire accidentally	Infirmary.
20	F.	3 yrs.	Oct. 31	10 hrs.	Stomach, right side, right arm, face, & head	Grandmother had gone out for water; whilst away the child's clothing caught fire. No one in the house besides the child	Linseed oil & lime-water were applied; then she was taken to the Infirmary.
21	F.	5 yrs.	Nov. 5	3 hours	All over, except feet and hands	Mother in a neighbour's house, leaving this, and another child two years' and a half old, alone	Infirmary.
22	M.	6 yrs.	Oct. 30	7 days	Bottom, thighs and belly	Was seen in the street in flames by a man, who ran up to it and tried to extinguish them. No one in the cellar from which the child had come. Mother did not return for four hours.	———
23	F.	6 yrs.	Nov. 3	4 days	Right arm, right side, chest, face, chin & neck	Clothes caught fire in trying to get some soot out of the chimney to clean her shoes with. Her sister, aged 10 years, in bed in the same room	Infirmary.
24	F.	4 yrs.	Oct. 4	57 days	Thighs, hands, & lower part of face severely	Was thrusting shavings into the fire with the poker, when her dress caught fire. No one in the room, grandmother up-stairs	———
25	F.	76 yrs.	Dec. 5	4½ hrs.	All over except one foot	Her clothes caught fire in lifting the kettle off the fire	Taken to Infirmary. She was of weak intellect.
26	F.	14 yrs.	Oct. 6	9 weeks	Both arms, neck, throat, right thigh, chest, & both hands	Her clothes caught fire in blowing the fire with the bellows	———
27	F.	37 yrs.	Dec. 2	13 days	Arms, chest, back, right ear, face, forehead, &c.	Bed curtains caught fire from leaving a candle burning near her bed, whilst she slept a short time before proceeding with her work	At the Infirmary. A very industrious woman.
28	F.	5 yrs.	Dec. 14	1 day	Both arms, head, face, and whole of the body, except the legs and feet	Went up stairs with some shavings in her pinafore, into a room where there was a fire. In five minutes came down again in flames	At the Infirmary.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death	Parts which were burnt.	How the Accident occurred.	Remarks.
29	M.	5 yrs.	Dec. 15	1 day	All over, except feet, legs, back, and face	The mother had gone out to beg, the child having had no meat that day. No one was in the cellar where the child lived	At the Infirmary.
30	F.	1½ yrs.	Dec. 12	46 hrs.	Breast & chin	Pulled over upon herself a small pan, containing boiling water. Many persons were in the room at the time	———
31	F.	17 yrs.	Dec. 27	7½ hrs.	All over the body	Clothes took fire. Not known how	Infirmary.
32	M.	5 yrs.	Dec. 28	7 hours	Stomach, arms, face & neck	Mother and father out at work. Three or four children in the room with this child, the eldest of whom was 12 years. Clothes took fire	———
33	F.	7 yrs.	Dec. 21	8 days	Right arm, chest, right side, neck, and belly. Left arm slightly.	Had been left in charge of a woman who went out for a qr. of an hour, and on returning found that the child had been burnt, & taken to the Infirmary	Infirmary.
34	F.	8½ yrs.	Dec. 27	2 days	From ankles up to the waist was one sore	On a dark morning she stepped into a pail of boiling water, and upset it.	Flour was applied immediately, and then treacle over the flour.
35	F.	87 yrs.	1840 Jan. 6	7 hours	Both arms, back, chest, neck, face, &c.	Whilst cooking sausages, and examining them with a candle, her cap took fire	Infirmary.
36	F.	5 yrs.	Jan. 4	——	———	Mother out at work. Child left in charge of a woman living in another room, who ran down on hearing the screams. The child had been trying to put the kettle further on the fire, when a cotton handkerchief round her neck caught fire	———
37	M.	5 yrs.	Jan. 7	3½ hrs.	All over the body, except feet and legs	Mother out on an errand at a neighbour's house, leaving this boy and another of the same age together. The other little boy said "*that William went up to the fire and lighted the end of his pinafore*"	Infirmary.
38	F.	4½ yrs.	Jan. 8	15 hrs.	Both arms & all over the body, face, neck, & thighs	Woman in charge of her had gone out for a few minutes for water. The child said that she had been warming herself, when her bedgown caught fire	Infirmary.
39	F.	4 yrs.	1839 Dec. 28	10 days	Right arm, right side, neck & shoulder	Left in a cellar with a baby in the cradle. Mother had gone out for a short time. Child supposed to have been lighting shavings. A man passing by heard its screams, and went in and extinguished the flames, and then took the child to the infirmary	Infirmary.
40	F.	8 yrs.	1840 Jan. 7	2 days	Face, hands, & thighs	Was left alone in the cabin of a boat, when his pinafore took fire. A man passing by heard the screams, and put him into the canal to put out the flames	Infirmary on the 8th of January.

Foreign Department.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE, PARIS

ACTION OF ERGOT OF RYE.

M. Piorry read reports on two subjects—one a work by M. Marchal, relative to "Tuberculization of the Bronchial Glands;" the other on a memoir by M. Arnal, "On the Action of Ergot of Rye, and its Employment in Internal Hæmorrhages."

In the latter memoir M. Arnal affirms that ergot contains a poisonous principle capable of destroying small animals. This principle is not soluble in oil or æther. He considers the powder to be the most potent preparation, and recommends it, therefore, whenever the extreme action of the medicine is required. The first toxic action of ergot is exercised upon the intestinal canal, in which it gives rise to an inflammation *sui generis*, with lesions not unlike those seen in typhoid fever. Ergot exercises also a notable alteration in the composition of the blood, rendering it more diffluent. When taken for a length of time it induces a condition resembling scurvy. It diminishes the force and frequency of the cardiac pulsations, to which action he attributes its hæmostatic powers in active hæmorrhages. The watery extract has also diuretic properties. He recommends its use in pneumonia, especially where active depletory measures are inadmissible.

CORRODING ULCER OF THE ANO-VULVAR REGION.

M. Huguier described an *esthiomenic* or *corroding ulcer* of the ano-vulvar region. He stated that this form of ulcer was sufficiently familiar in the face under the name of lupus, but had been confounded with other diseases when it appeared in the female genital organs.

In this region, as elsewhere, M. Huguier attributes the origin of the ulcer to the scrofulous habit, or to the combined effects of this habit and syphilitic taint. He has generally seen it in young women, and admits the three forms of ulceration described by Biett, viz.,—1. Superficial lupus. 2. Corroding lupus. 3. Lupus with hypertrophy. The diseases with which it may be confounded are stated to be—syphilitic ulceration, elephantiasis, and simple hypertrophy of the tissues.

M. Chassaignac, readan essay on the "Employment of Ice in Hæmorrhage from Mucous Membranes," which is destitute of interest.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DES SCIENCES, PARIS.

ÆTHER AND CHLOROFORM.

The Academy has received several communications relative to chloroform. The first, by MM. Dumeril and Demarquay, is an exceedingly elaborate production, entitled "Researches on the Modifications of Animal Temperature by Æther and Chloroform." The summary of this memoir will be found in our Retrospect.

M. Gruby also read an essay on the "Modifications of the Blood by Chloroform." According to him chloroform, so far from rendering arterial blood of a venous hue, actually increases its arterial tint.

M. Bouisson's essay on the "Comparative Merits of Æther and Chloroform" is an important contribution. He commences by stating his conviction that chloroform will not replace æther, but that both have their drawbacks as well as advantages. He does not think chloroform suitable to prolonged operations, but prefers it in those of short duration. In lengthened operations he places great confidence in æther. M. Velpeau disputed these opinions, affirming that chloroform ought in all cases to be preferred, on account of the rapidity of its action, and the freedom from excitement generally exhibited by patients under its influence.

COMPOSITION OF BLOOD IN SCURVY.

MM. Chatin and Bouvier gave some further experiments on the "Composition of the Blood in Scurvy." They determine—1. That the fibrin is increased in quantity as has already been shewn. 2. That the plasticity of the fibrin is diminished. 3. That the globules are diminished. 4. That the albumen loses its coagulable properties. 5. That the alkalinity of the blood is increased.

ON THE VOICE.

M. Segond addressed a second memoir on the *voice*, more particularly the *inspiratory voice*. The memoir may be thus recapitulated:—1. The production of voice is not necessarily connected with expiration; man possesses the power of speaking during inspiration. 2. Ventriloquism is the management of the inspiratory voice. 3. Singing birds exercise both kinds of voice, which accounts for the variety of their notes. 4. The voice of some batrachians is exclusively inspiratory.

BATHS IN ACUTE MANIA.

M. Brierre de Boismont read some observations on "Prolonged Baths and Douches, in the treatment of Acute Mania." The results are thus stated:—1. Acute mania may be cured by the above means in one or two weeks. 2. The duration of the bath should be in general from ten to twelve hours. 3. The douches should be equally prolonged, and suspended only when the patient is quiet. 4. If no benefit is derived after eight or ten of these baths, they should be abandoned. 5. Acute mania is the form most amenable to this treatment; next simple acute delirium, delirium tremens, &c. 6. When acute mania is associated with ataxic symptoms, or refusal of food, the treatment will not succeed.

The author maintains that in general no ill effects follow the prolonged bathing, and that it is applicable to certain forms of hysteria.

ROYAL COLLEGE OF PHYSICIANS: PROPOSED NEW CHARTER.

[We are now enabled to lay before our readers officially, the clauses of the proposed new Charter, as they at present stand. The preamble and conclusion are the same as in the draft which was published in the last number of the *Journal*.]

1. That the said corporation shall henceforth be styled —"The Royal College of Physicians of England."

2. That the said corporation shall consist of fellows and members, including a president and council, four vice-presidents, four censors, a treasurer, and a registrar.

3. That all the present licentiates of the said corporation shall be members of the said corporation.

4. That each of the present extra-licentiates of the said corporation may be admitted a member of the said corporation on the production to the said censors of the said corporation of testimonials of character which shall be satisfactory to the said censors, and on his assuring the said censors that he is not engaged in the practice of pharmacy, and on his paying to the said corporation a fee of fifteen pounds fifteen shillings, exclusive of the stamp duty.

5. That every person practising as a physician in England or Wales, and who shall have taken the degree of doctor in medicine at any university in the United Kingdom of Great Britain and Ireland, after regular examination at least three calendar months previously to the date of these our letters patent, and also every person who shall have received a licence to practise physic from either of the Universities of Oxford or Cambridge, and also every person practising as a physician in England or Wales, who shall have taken the degree of doctor in medicine at any foreign university at least three months previously to the date of these our letters patent, after regular examination, and after having resided during a period of not less than two years in an university, and also every person practising as a physician in England or Wales, who shall have been for a period of not less than three months previously to the date of these our letters patent a fellow of the Royal College of Physicians of Edinburgh, or a fellow of the Royal College of Physicians of Dublin, who not having taken the degree of doctor in medicine in any British or foreign university, shall have resided during a period of not less than two years in an university, and who shall have been admitted as a fellow of such Royal College of Edinburgh or Dublin, as the case may be, after regular examination, provided such person shall have attained the age of twenty-six years, and shall not be engaged in the practice of pharmacy, shall, at any time within twelve calendar months from the acceptance of these our letters patent by the said corporation, in the manner mentioned in the act of parliament hereinbefore stated to have been passed in the present year of our reign, be admitted a member of the said corporation, without any examination, on the production to the censors of the said corporation of his diploma, and of such testimonials of character and professional qualifications as shall be satisfactory to such censors, and on his proving himself to be of the said age, and on his assuring such censors that he is not engaged in pharmacy, and on his paying to the said corporation a fee of fifteen pounds fifteen shillings, exclusive of the stamp duty.

6. That any person who, after regular examination, shall have taken a degree in medicine at any university in the United Kingdom of Great Britain and Ireland, or at any foreign university to be from time to time recognized by the said corporation, and who shall have attained the age of twenty-six years, and shall not be engaged in the practice of pharmacy, and shall have gone through such course of studies, and who shall have passed such examination before the censors of the said corporation, touching his knowledge of medical and general science and literature, and complied with such other regulations as are or shall be required by the by-laws of the said corporation, shall be entitled to become a member of the said corporation without being subject to any other election.

7. That the present fellows of the said corporation shall continue to be fellows of the said corporation.

8. That every member who shall be admitted a member of the said corporation, as hereinbefore mentioned, who shall be desirous of becoming a fellow of the said corporation, shall, after the expiration of one year from the time of his having been examined for his licence to practise medicine, be capable of being elected a fellow thereof, provided he shall, in addition to the examination hereinbefore mentioned, at any time after the expiration of one year from that examination, have passed such further examination before the censor of the said college, touching his knowledge of medical and general science and literature, and complied with such other regulations as are or shall be required by the by-laws of the said corporation; provided, nevertheless, that such member shall not be capable of being actually elected a fellow as aforesaid, unless or until he shall have attained the age of thirty years.

9. That during the period of five years, to be computed from the date of these our letters patent, every person, who, according to the present regulations of the said corporation, might be elected a fellow thereof, shall be capable of being elected a fellow thereof on the terms on which he would have been entitled to be elected a fellow thereof if this charter had not been granted.

10. That after the expiration of the period of five years, to be computed from the date of these our letters patent, the council of the said college shall have the power to nominate yearly two members thereof, who, in the opinion of the council, shall have distinguished themselves in the pursuit of science or literature, to be proposed to the fellows for election as fellows, provided the members so to be nominated shall have been members of the said corporation for a period of not less than four years.

11. That the fellows of the said corporation shall be elected at a meeting of the fellows, and such meeting shall be held yearly, on the 25th day of June, unless the same shall fall on a Sunday, and then on the 26th day of June, and the first of such meetings shall be held on the 25th day of June, (or 26th day of June,) 18 .

12. That if it shall at any time hereafter appear, that any present or future fellow or member of the said corporation shall have obtained admission to the said corporation by any fraud, false statement, or imposition, or that he shall have violated any by-law, rule, or regulation, of the said corporation, then, and in every such case, and after such previous notice to, and such hearing of, such fellow or member, as, under the circumstances, the president and censors of the said corporation shall think proper, it shall be lawful for a majority of the fellows present, at a meeting of the fellows, to declare such fellow or member to be expelled from the said corporation, and thereupon every such fellow or member shall cease to be a member or a member and fellow of the said corporation, as the case may be accordingly, and all the privileges granted to such member or member and fellow, as the case may be, shall cease and be extinguished.

13. That the present president of the corporation shall continue to be president of the said corporation until a new president shall be actually appointed in his place,

and that upon the day next after Palm Sunday, in the year 18 , and on the same day in every subsequent year, a new president of the said corporation shall be elected at a meeting of the fellows of the said corporation, but the retiring president shall always be capable of being re-elected, and every president shall remain in office until the actual election of the new president.

14. That at the meeting of the fellows held for the election of the new president, the council of the said corporation shall, out of the first fifty fellows in the list of fellows of the said corporation, nominate some one of such fifty fellows to be proposed to the fellows of the said corporation, to be by them elected president; but if the fellow so nominated shall not be elected president by a majority of the fellows present at such meeting, another fellow shall in like manner be nominated by the council, out of the first fifty fellows in the list of fellows, to be proposed as aforesaid, and so on, until a president shall have been elected. The election of president shall be taken by ballot, and in case of any difference in the council concerning their selection of a president, the president nominated by the majority shall be proposed to the fellows, and in case of an equality of votes in the council, the senior fellow so nominated shall be so proposed.

15. That in case of the death, or resignation of the president for the time being, a new president shall with all convenient speed be elected in his place, such election to be made in all respects in the same manner as is provided by the last preceding regulation.

16. That at any time before or at the meeting of the fellows of the said corporation, after the meeting of the fellows at which the president of the said corporation shall have been elected, the president so elected shall appoint four fellows out of the first fifty on the list of fellows, which shall be called vice-presidents, any one of whom may act as president in the temporary absence of the president, upon such president expressing his desire to such effect to any such vice-president, in writing, or to the registrar; and in case of the death of the president, the first vice-president, for the time being, in the list of vice presidents, shall act as president until a president shall have been appointed, and the present president of the said corporation shall, at the meeting of the fellows of the said corporation next after the granting of these our letters patent, appoint four vice-presidents for the purposes aforesaid.

17. That the vice-presidents shall cease to be vice-presidents when a new president shall have been appointed in the place of the president by whom they were nominated.

18. That there shall be sixteen fellows on the council of the said corporation.

19. That the present council of the said corporation shall continue to be the council of the said corporation until a new council shall have been actually elected in their place, and that, on the twenty-second day of December next, four fellows shall be elected to make up the number of the council to sixteen, and that, on the twenty-second day of December, 18 , and on the same day in every year, (except when the same shall fall on a Sunday, and then on the twenty-third day of December,) four of the council shall go out of office and four fellows shall be elected of the council, but the fellows going out of office shall not be re-eligible until they have been one year out of office, and the fellows to be elected as aforesaid, shall remain in office until others shall have been actually elected in their place, and that on the same day other fellows shall be elected to the council to fill up vacancies occasioned by death or resignation since the last election.

20. That the council shall be elected by the fellows out of their own body, by ballot, either by list or otherwise, as the said corporation shall from time determine by the by-laws.

21. That in addition to the sixteen fellows so elected, the president, censors, and treasurer of the said corporation shall *ex officio* be of the council of the said corporation.

22. That the present censors of the corporation shall continue to be the censors thereof until new censors shall have been actually elected in their place; and that on the day after Palm Sunday, in the year one thousand eight hundred and , and on the same day in every subsequent year, four new censors shall be elected; and censors going out of office shall be re-eligible and the censors to be elected as aforesaid shall remain in office until other censors shall actually have been elected in their place.

23. That on the day for electing censors the council shall nominate four of the fellows of the said corporation to be proposed to the fellows, to be by them elected censors; but if any fellow or fellows so nominated shall not be elected a censor or censors by a majority of the fellows present at the meeting, another fellow or fellows shall be nominated at such meeting by the council, to be proposed to the fellows, and so on until four censors shall have been elected. The election of censors shall be taken by ballot. In case of a difference in the council, concerning the nomination of censors, the censors nominated by the majority shall be proposed to the fellows; and in case of an equality of votes in the council, the president shall have a casting vote.

24. That in case of the death or resignation of any of the censors for the time being, a new censor shall, with all convenient speed, be elected in his place, such election to be made in the same manner as is provided by the last regulation.

25. That the present treasurer of the corporation shall continue to be treasurer of the said corporation until a new treasurer shall be actually elected in his place; and that on the day after Palm Sunday, in the year one thousand eight hundred and , and on the same day in every subsequent year, the president shall nominate one of the fellows to be elected by the fellows as treasurer, in the same manner, in all respects, as is before appointed for the election of censors by the fellows, and the treasurer shall be re-eligible, and every treasurer shall remain in office until a new treasurer shall be actually elected in his place.

26. That in case of the death or resignation of the treasurer for the time being, a new treasurer shall with all convenient speed be elected in his place, such election to be made, in all respects, in the same manner as is provided by the last preceding regulation.

27. That the present registrar of the said corporation shall continue to be the registrar of the said corporation until a new registrar shall be actually elected in his place; and that on the day after Palm Sunday, in the year 18 , and on the same day in every subsequent year, the president shall nominate one of the fellows to be elected by the fellows as registrar, in the same manner, in all respects, as is before appointed for the election of censors by the fellows, and the registrar shall be re-eligible, and

every registrar shall remain in office until a new registrar shall be actually elected in his place.

28. That in case of the death or resignation of the registrar for the time being, a new registrar shall with all convenient speed be elected in his place, such election to be made in all respects in the same manner as is provided by the last preceding regulation.

29. That the president, council, censors, treasurer, and registrar, shall be considered as remaining in office during the whole of the day on which their successors shall be elected.

30. That the said corporation may, from time to time, by a by-law, change the day hereby appointed for any election to take place, and if, from any cause whatsoever, any election shall not take place on the day hereby or by any by-law appointed for that purpose, the same shall take place on some other day appointed for that purpose by the said corporation.

31. That proxies shall not be allowed at any election.

General Retrospect.

PATHOLOGY.

ON THE URINE IN TYPHOID FEVER.

M. Martin Solon recently (Nov., 1847,) read at the Académie an interesting paper upon the condition of the urine in typhoid fever, the principal points of which are thus summed up—1. The urine in typhoid fever is less abundant, higher coloured, and generally more dense, than in health. 2. It is as acid as in the normal state, and sometimes more so. 3. It is rarely alkaline, but in consequence of its large proportion of urea, it readily passes into the condition of alkalescence. So abundant is the urea, that sometimes a nitrate may be at once formed by the addition of nitric acid without any preliminary evaporation,—a density of from 1.030 to 1.036 indicating this condition. 4. Generally transparent, the urine is sometimes clouded with mucus, (the *enœorema* of the ancients,) or by an excess of too-sparingly soluble salts, which give it a *tomenteux* appearance, and which give rise to sediments, formed especially of uric acid and the urates with colouring matter. 5. That critical signs deduced from these appearances are not to be depended upon. 6. That in transparent urine, nitric acid sometimes gives rise to no re-action, but in other cases produces a *cloudiness* immediately. 7. The same thing is observed in "tomentous" urine, when rendered clear by filtering. 8. That this cloud, of a peculiar tomentose aspect, formed by a bi-urate of ammonia, but the nature of which is perhaps not yet entirely known, is seen especially at the period of the resolution of typhoid fever and acute diseases, which it precedes and announces; and according to our clinical observations (in fifty-four cases,) possesses a *critical* value which deserves attention. 9. That the bile undergoes a notable alteration during typhoid fever, which is doubtless the cause of the appearance of *biliverdin* in the urine. 10. That the urine sometimes becomes temporarily albuminous during the course of acute diseases; but that the congestion of various organs, especially the kidneys, and the especial tenuity of the blood in typhoid fever, render such temporary albuminuria far more common in this than in other affections. 11. Temporary albuminuria is especially seen in severe cases of typhoid, and generally gives rise to the most unfavourable prognosis. 12. Temporary albuminuria may sometimes become continuous, and the kidneys then exhibit the usual pathological characteristics of confirmed albuminuria. 13. The inspection of the urine throws light upon the progress of a case of typhoid fever, and may serve as a means for the direction of its treatment.—*Bulletin de l'Académie*, tom. 13, p. 398.

CONDITION OF THE GUMS IN PHTHISIS.

Dr. Frederick mentions a brick-red line on the gums of phthisical patients near the teeth. It is most marked over the incisor and canine teeth. Since his attention was turned to the symptom, he has observed it in numerous cases, but cannot say at what period of the disease it first shews itself. He has not met with it in other diseases.—*Union Médicale*, 1848. No. 5.

CARCINOMATOUS AFFECTIONS OF THE SPINE.

Dr. Bühler has lately described three cases of this incurable but interesting and very important disease, of which there are few records, and of those which have been recorded are all doubtful, except the four cases by Mr. Cæsar Hawkins, in the "Medico-Chirurgical Transactions" of 1841. Dr. Bühler's cases are remarkable, insomuch that the affection presented itself apparently as a primary disease of the vertebræ, as in one of Mr. Hawkins's, in whose three other cases carcimona had already been developed in the mammæ or testes. Dr. Bühler's first case occurred in an actor, a remarkably fine and well-built young man of 27 years of age. The second was that of a man of 69, who from his youth had been scoliotic, or humpbacked, in consequence of a fall. The third was a woman of 42, who asserted she had had no previous illness. The first case was admitted to the hospital for paraplegia of the legs; the two other cases were sent in from the country as chronic rheumatism, for which they were at first, and unsuccessfully, treated. All three exhibited in the progress of the disease the greatest similarity of symptoms, the most prominent of which were excessive pains which yielded to no remedy; these were at first confined to the back, but soon they extended to other parts of the body, and never ceased. At times they were most severe, particularly during the night, depriving the patient of all sleep. Pressure upon the spinous processes and neighbouring soft parts, and any motion of the body, materially increased the sufferings; the most easy posture was half recumbent, in which the patients generally remained. There were frequent spasmodic twitches, sometimes in one group of muscles, sometimes in another; clonic spasm of the legs and starting of the whole body, accompanied with severe pain, but without any disturbance of the sensorium. The respiration was generally quickened, and sometimes genuine asthmatic dyspnœa, with great constriction of the chest, took place. Other groups of muscles were at times attacked with tonic spasms; thus, the thighs were drawn up upon the abdomen, the muscles of which were frequently violently contracted. Constipation and retention of urine existed; at last,

however, the sphincters became paralysed, and then both fæces and urine passed involuntarily. According to the higher or lower seat of the disease, the upper or lower extremities were paralysed, and sensibility partly or wholly extinguished. Occasionally formication and numbness were complained of; and motion, either voluntary or otherwise, always occasioned great pain. No scoliotic change in the form of the spine was observed, except in the young man, in whom the curvature became greater than natural; nor was the usual carcinomatous expression of countenance present, until near the end, when general cachexia was developed, and other organs participated in the disease. The progress was slow, death ensuing from the sixth to the ninth month. On dissection, the vertebræ were found softened, infiltrated by carcinoma, or wholly destroyed, and the whole spine more or less affected. The bones of the pelvis, femur, and sternum were also involved, and evidences of disease were found in the brain, lungs, pleuræ, liver, kidneys, and several lymphatic glands. ("Ueber Wirbeltuberkulose in einer bisher noch nicht beachteten form, und über den Krebs der Wirbelsäule von Dr. Heinrich Bühler." 1847.)—*Medical Times.*

SURGERY.

EXTIRPATION OF CAPILLARY ANEURISM BY LIGATURE.

Mr. Luke advises that the nævus should be intersected with a larger number of threads than is commonly done, so that smaller sections of the tumour can be strangulated. His plan is to thread a sufficient number of needles upon the same thread, leaving an interval of twelve or fourteen inches between each. The needles are then introduced one after another at a distance of half an inch, the first and last needle being inserted at a point beyond the morbid structure; the needles are then cut off, and the contiguous ends are tied each way.

[We do not see that any advantage is thus obtained more than would be afforded by the same number of needles, with separate double threads.]—*Med. Gazette*, April 7, 1848.

TREATMENT OF STRUMOUS OPHTHALMIA BY CAUTERIZING THE NOSTRIL OF THE AFFECTED SIDE.

Dr. Edwards writes in favour of the method of treating strumous ophthalmia, first advocated by M. Morand. The latter having observed that a swollen and inflammatory condition of the nasal mucous membrane often preceded or accompanied the eye affection, was led to treat it by the application of lunar caustic, either in substance, or strong solution, to the part.

Alluding to this treatment, Dr. Edwards remarks that he had not observed the inflammatory redness to the extent mentioned by M. Morand, in most cases that came under his care, but that he had done so in some which came to him early. He mentions a tumid upper lip as a very frequent concomitant of strumous ophthalmia, and states that cauterizing the nostril removes this complication sooner than any other treatment. He is not able to say whether this treatment prevents relapses; five cases are adduced in illustration. It must be mentioned that the usual internal medicines are given at the same time.—*Lancet*, Apri 18th.

THE ACTIONS AGAINST THE MIDLAND RAILWAY COMPANY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I cannot but think that in the comments appended to your report of the recent trials at Warwick against the Midland Railway Company, your zeal for the interests of our profession has, to a certain extent, outrun your discretion; at all events, I am not by any means disposed to apply the terms "*mean*," and "*pitiful in the extreme*," to the conduct of the Company on that occasion. I quite agree with you that a fair and reasonable recompense was due to the practitioner who was called in to take charge of the man Higgins, after the receipt of his accident, and I by no means desire to make any comment on the amount of Mr. Sands Cox's demand, which, for the services performed by a surgeon of his eminence, seems moderate enough. It does, nevertheless, strike me, that in this, as in many other instances I have read of, with pain and regret, there is a palpable deviation on the part of our profession from the course which is required and expected at their hands, in cases of this nature; so much so indeed, that it would almost seem as if the moment a medical man got hold of a public company as his paymaster, he considered himself entitled to put them to whatever amount of expense he pleased. That such is an exception to the rule which ought to prevail, I am willing to hope and believe; but as far as the published reports of trials of this kind throughout the kingdom are evidence, I must say that the sums claimed for professional services are frequently out of all proportion to the service rendered, and almost always at utter variance with the station in life of the party attended, and the probable amount which would have been charged in the event of the patient himself being the person liable to pay.

Let us now see how these observations bear on the case in question. From the report of the trials, we find that the man Higgins, a person in humble circumstances, met with an injury on the Midland Railway, on the 9th February, 1847, by which one of his legs was so much crushed, as to render amputation of the limb necessary, and that he was placed by the station master, Mr. Bladen, under charge of Dr. Davies, of Coleshill; we further find, that in the course of the same evening he was attended by three other surgeons of the same place, making four, together in consultation, but that the whole united body were unable to decide whether it was proper to cut off the man's leg or not! They therefore sent for Mr. Sands Cox, from Birmingham, who not only decided the point in the affirmative, but was also so obliging as to relieve them from the trouble of the operation. The man it appears got well, but the result of all this vacillation and want of self-confidence in the Colesbill surgeons is, that for the amputation of a leg, and the subsequent attendance, a claim is made against the company but little short of seventy pounds!! Now, I cannot conceive, that this is a fair position in which to place a public company any more than a private individual. *Why* could not

Messrs. Davies and Son, Mr. Barker, and Dr. Bourne, have come to a conclusion without the aid of Mr. Cox?—and even if they could not, why should Mr. Cox have performed the operation, or have received more than one single consultation fee for his opinion, which would probably have been five or six guineas? I confess myself at a loss for an answer. Ten guineas to Dr. Davies for the amputation; ten guineas for the subsequent attendance; and, if you will, six guineas to Mr. Cox, would have been a fair remuneration to the medical men for a person in the circumstances of life of Higgins; and yet you do not hesitate to charge the Railway Company with "*mean*" and "*pitiful conduct*," because, stung by the enormous amount of the demand upon them, an attempt is made to lessen, or to escape from it, entirely.

Now, Sir, it has been my lot to serve the Midland Railway Company frequently in my professional capacity, and I have attended on several severe accidents on that portion of their line adjoining my residence. On every occasion they have acted in the most honourable manner, neither questioning the amount, nor deducting a shilling from my accounts, and I have always been amply paid for my time and trouble; and yet, if I was called this night to one of their third-class passengers with a crushed limb, requiring immediate amputation, and for myself and another surgeon called in at my suggestion to assist my own wavering judgment, I put them to an expense of nearly seventy pounds, I question very much whether I should get my money without litigation, or should receive or deserve to obtain their confidence on any future occasion. I am willing to admit that for the most part medical men are underpaid for their services, but I cannot allow that this is any reason why a public company, or a private individual, against whom a legal liability for payment exists, should be fleeced or imposed upon; and I affirm it as my opinion, that the only honourable or even honest course for a medical man to pursue in making his professional charge, is to look at the station in life of his patient, as well as the capability of his employer to pay. What, for instance, would be thought of an innkeeper, who, receiving orders from a nobleman to take care of a poor man accidentally injured by one of his servants, placed him in the best apartment of his house, at two or three guineas a-day, or fed him with turtle and champaign, when mutton and beer would answer the purpose equally well? My belief is, and it is the result of very many years of experience and observation, that the remedy for these complaints on the part of the medical profession lies very much in their own hands, and that to their own recklessness and rapacity most of these disputes are owing. Railway companies in particular I am confident are more sinned against than sinning.

I have at this moment a patient with injury of the spine, arising out of a collision of trains on the London and North Western Railway, and I will undertake to say that Company will pass my account when they receive it without comment; and why? because it would not enter into my mind to charge them at a higher rate than I should charge the same patient if the accident had happened in his own farm-yard. Let the medical profession, then, follow this rule; let their charges be remunerative, but not extravagant: above all, let them be fairly proportioned to the station in life in which the sufferer is placed, and it will much surprise me, from the experience I have of public companies, if they do not generally meet us in the same spirit of fairness and liberality. I regret the length at which I have troubled you, but the subject is one on which I have thought much, and felt strongly, and in my judgment is one in which the honour and welfare of our profession are deeply involved. I enclose my name,

And am, Sir,

Your obedient servant,

A MIDLAND COUNTIES' SURGEON.

PRINCIPLES OF MEDICAL LEGISLATION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Inasmuch as it does not appear Mr. Ancell has succeeded in shewing that the proposed "Principles of Medical Legislation," are not in direct opposition to the principles advocated by the Provincial Association during so many years and on such repeated occasions, I should hardly have thought it necessary to claim any space in the Journal for a reply to the comments which he has made in this week's number upon my communication in the previous number, had it not been that his remarks appear rather to depart from a fair reply to the objections urged against the proposed new incorporation, for the purpose of attacking the Fellows of the College of Surgeons, and imputing unworthy and selfish motives to myself.

1st. Mr. Ancell is pleased to assert that I "repudiate a representative collegiate establishment," merely because I happen to be a Fellow of the College of Surgeons, and that I wish to deny to the greater part of the profession a right or privilege which I possess myself. I am not aware that in my letter, or on any other occasion, I have said a word which would justify such an inference. It is a gratuitous assumption which it might have been as well to have had some evidence in support of, before venturing to hazard. It so happens that I have both publicly and privately maintained precisely the contrary. Soon after the granting of the Charter to the College of Surgeons, I wrote to the Council and remonstrated with that body upon the exclusive character of several parts of the Charter, and in some observations upon the state of the medical profession, published at the time Sir James Graham introduced his first bill into the House of Commons, I distinctly stated, that in my opinion, the representative system in the various Colleges is the only fair and equitable one. Should Mr. Ancell do me the honour to read the copy of these observations which I have taken the liberty to send him, he must admit his erroneous assumption. In my letter in the Journal I did not especially allude to the subject of representation, simply because it appeared to be unnecessary; I thought there was comparatively little difference of opinion upon it; and I must confess that I do not even now comprehend

how a disapproval of Mr. Ancell's favourite scheme can with any fairness be construed into a disapproval of fair representative government. It is quite within the bounds of possibility, that other Colleges than the proposed one may possess this advantage. Indeed I fancy the charge made by Mr. Ancell, would, to those who know my opinions, appear to border upon the ludicrous. By many I should rather labour under the supposition of looking with too great a favour and trust to representative government than of repudiating it as Mr. Ancell imagines. His inference is about as logical as the connection, in the old story, of Godwin Sands and Tenterden steeple.

2nd. I stated that I objected to the proposed "principles" because I believed them to be at total variance with that principle which our Association has for so many years uniformly declared to constitute the *only satisfactory, safe, and just basis*, for medical legislation to rest upon,—viz., one uniform primary qualification, as tested by one common examination, compulsatory upon all, and affording common privileges to all; and I must still crave Mr. Ancell's pardon in being so dull, as either not to understand, or, understanding, not believing, how three distinct grades, with three totally distinct and very dissimilar examinations, conferring as different privileges, can constitute uniformity of qualification in any shape or form, or even afford a much better approximation to it than now exists in this country. The new institution may have another name, and new managers may make their *debut*, but in my opinion essentially it will be but a modified Apothecaries' Company. Now, I must confess, that I feel so much gratitude to this body for the good it has effected, that if any analogous institution is to exist, my suffrages would be rather in favour of the prolongation of the old, than the usurpation of a new body.

3rd. Mr. Ancell says he does not believe that I should confer any boon upon the profession, if I were to succeed in persuading the College of Physicians to lower their standard of qualification. I am not conscious of having in my letter, or at any other time, said a word from which an inference could be drawn that I wished either the College of Physicians or any other college to lower their standard. Upon this point Mr. Ancell need not be apprehensive. If the wish, however, to make every member of the profession prove that he possesses a competent knowledge of its various branches, by undergoing a searching and practical examination upon it generally, be likely to lower the standard of qualification, I must plead guilty to the charge, not otherwise.

4th. Mr. Ancell says, that the proposed new college is to examine and license to practise in surgery. This is denied by the authorities of the College of Surgeons, and the fact of a candidate being compelled to undergo an examination at the College of Surgeons, supports the denial, but the parties most interested must settle this matter among themselves.

5th. I must express my surprise that Mr. Ancell should have permitted himself to state that I have directly or indirectly imputed inferiority to the members of the College: such an idea never entered my head. I did not say a word about the members of the College. In stating that a new institution, organized as the proposed principles shew the new college, if it be chartered, will be, must necessarily in the very nature of things be not equal in public or professional estimation to the Colleges of Physicians and Surgeons, I only gave utterance to the opinion of every medical man with whom I have spoken upon the matter, and what every impartial observer believes and knows will be the case, and which I cannot but think Mr. Ancell himself, were he not influenced by parental fondness, would also perceive. Indeed, if he will read what he has said respecting the requirements of the College of Physicians, it appears doubtful if he does not unconsciously even now mentally admit this.

Mr. Ancell has been pleased to impute motives, not the most honourable or impartial, for my opinions. I will not retort upon him; otherwise the emphasis with which the words Honorary Fellow, and the frequency of the term Fellow of the College of Surgeons are introduced in his letter, as well as the whole tone of his remarks, would fully justify me in imputing his great zeal in favour of a new college to the circumstance of his not being a Fellow of the old; but I will not do so. Doubtless he thinks he is acting for the best interests of the profession. But I will venture to suggest for his candid consideration whether, in differing in opinion from him, especially seeing that I have the advantage of being altogether in agreement with the convictions of the Provincial Association, it be not very possible that I may in fairness claim to be actuated by as much honesty and uprightness of opinion as himself. Nay, that I may possess an equal respect for my professional brethren. The Charter of the College of Surgeons was not under discussion, I therefore did not drag it in, but if it affords any consolation to Mr. Ancell, I may inform him, that with him, I think that in the first instance, the selection of fellows was arbitrarily made,—that doubtless many omitted were more deserving than several admitted to the fellowship. That I should be glad to see gentlemen like himself, (and it is only by referring to the *Medical Directory*, induced by the tone of his letter, that to my surprise, I find he is not one,) among the Fellows of the College of Surgeons, and farther, that although I think the new Charter in many respects a great improvement upon the old, I am clearly of opinion that a general measure for the regulation of the whole profession ought to have preceded the granting of new charters to the Colleges of any section of the profession.

I am, Sir, faithfully yours,

THOMAS NUNNELEY.

Leeds, May 6, 1848.

PRINCIPLES OF MEDICAL LEGISLATION.

MEMORIAL FROM BRIGHTON.

To the Right Honourable Sir George Grey, Baronet, Her Majesty's Principal Secretary of State for the Home Department,

Sheweth,—

That your memorialists being legally qualified members of the medical profession, have read with approbation a paper entitled, "Principles" for a general measure of medical reform, which has been agreed upon by the joint Committee of the Royal Colleges of Physicians and Surgeons, the Society of Apothecaries, and the National Institute of Medicine Surgery and

Midwifery, and which your memorialists believe has been submitted to the head of the Home Department.

The undersigned are of opinion that a legislative measure founded on those principles will conduce to the welfare of the public, and will be generally satisfactory to the medical profession.

Your memorialists therefore pray, that for an act of the legislature, Her Majesty's Government will adopt those principles of medical reform.

George Drummond, M.R.C.S., L.S.A., Brighton; Thomas Allen, M.D., Brighton; John Dill, M.R.C.S., Brighton; Thomas Blair, M.D., Brighton; George Hall, M.D., Oxon., Brighton; Andrew Plummer, M.D., Brighton; John Lawrence, F.R.C.S.E., Brighton; James Arnott, M.D., Brighton; Edward Dix, M.R.C.S.E., Brighton; Jas. Turner, M.R.C.S., L.S.A., Brighton; Jas. W. Wilson, M.D., Brighton; George Royde, M.R.C.S.E., L.A.H., Brighton; Augustus Franz, M.D., M.R.C.S., Brighton; John Cordy Burrows, M.R.C.S.L., and L.A.C., Brighton; William Kibbell, M.D., Brighton; J. R. Simonds, M.R.C.S., Eng; Edmund J. Furner, Surgeon; Richard Newnham, Surgeon; Robert Taylor, F.R.C.S., and A.C.L; E. Wildman Whitehouse, M.R.C.S., and L.A.H., Brighton; T. B. Winter, M.R.C.S., and L.S.A.; William King, M.D., Cantab., 23, Montpellier Road; Thomas Andrews, Surgeon, Montpellier Road.; Thomas Yates, M.D.; James Oldham, Norfolk Square; M. D. Nugent, M.D., F.R.C.S., Lond. and Dubl., Brighton; William Scott Watson, M.R.C.S., L.S.A.; George S. Jenks, M.D., Brighton; Jenkin Jones, M.D., Brighton; George Lowdell, M.R.C.S., L.A.C., Brighton; Gavin Eliott Pocock, M.R.C.S., L.A.C., Cannon Place; Richard Rugg, M.R.C.S., L.A.C., Brighton; T. Paine, Surgeon, Brighton; George Tatham, M.R.C.S., L.A.C.; W. B. Rowe, M.R.C.S., L.A.C., Brighton; J. King Dingle, M.R.C.S., L.A.C.; Thomas Barker, M.D., Brighton; W. R. Mott, Surgeon, formerly Surgeon 47th Regiment, Foot; W. Adam Maiben, M.R.C.S., L.A.C.; J. T. Gardner, M.R.C.S., L.A.C., St. James's Street; W. H. Fry, L.A.C., Dorset Gardens; William Wilton, M.R.C.S.L., L.A.C., St. James's Street; Thomas B. Horne, M.R.C.S., L.A.C.; Hampton Weekes, M.D.; Robert Caudle, Surgeon, Brighton; William Verrall, Surgeon, Brighton; R. M. Philpott, Brighton; S. K. Scott, M.R.C.S., L.A.C.; Geo. Battock, Surgeon, Brighton; John Lawrence, jun., Brighton; B. Thos. Seabrook; Robert Dix, Surgeon, Brighton; Henry Sutton, Surgeon Accoucheur, Brighton; E. D. W. Mitchell, M.R.C.S., L.A.C.E., Brighton; James Ansley Hingeston, M.R.C.S.L.

Medical Intelligence.

THE FRENCH NATIONAL ASSEMBLY.

Several members of the medical profession have been returned to the National Assembly, among others MM. Buchez, Recurt, Trelat, Gerdy, and Trousseau. M. Buchez has been elected President of the Assembly, and M. Recurt one of the Vice-Presidents.

NEW TREATMENT OF SCARLET FEVER.

Dr. Schneemann, Physician Royal, and Member of the Medical Council at Hanover, has, in his recent work on scarlet fever, proved the inefficacy of all the remedies hitherto employed against this malady. His new and simple mode of treatment, tested by experience, consists in *not* allowing the patient, who continues his usual diet, to go to bed, in having the sick-room frequently ventilated; and chiefly in rubbing the body with bacon several times a day. This is the whole system, which is said to have worked astonishing cures!!!—*Hamburgh Beobachter*, Febr. 1848.—From *Aris's Birmingham Gazette.*

ST. GEORGE'S SCHOOL OF MEDICINE.

May 1st, 1848.

Distribution of prizes and presentation of a portrait and lithograph to Dr. W. Vesalius Pettigrew. Sir James Clark, Bart., F.R.S., in the chair.

The report showed the increasing prosperity of the school, also the greater amount than usual of diligence and emulation amongst the students, many more subjects having been dissected during the past session than for the eight or nine previous sessions. Allusion was made to the death, in August last, of Mr. T. A Elliott, a former Assistant-Demonstrator at the school; and also to the decease of Mr. Liston, who lectured at this school for two sessions. It was proposed by Mr. R. D. Grainger, and seconded by Admiral Sykes, that the report be adopted.

The prizes were then awarded as follows, the sealed envelopes being broken open as the mottos were called, and the successful candidates thus for the first time known either to lecturers or students:—

Senior Anatomy.—*Silver Medals*—Mr. R. E Price, Mr. Herbert Brown. *Certificates*—Mr. Finnimore, Mr. Turner.

Junior Anatomy.—*Bronze Medal*—Mr. T. Ball. *Certificates*—Mr. Bullock, Mr. Goodall, Mr. Jones.

Medicine.—*Prize*—Mr. Allen. *Certificate*—Mr. G. Fast.

Chemistry.—*Prize*—Mr. T. Ball. *Certificates*—Mr. Bullock, Mr. Warden, Mr. V. Jones.

Materia Medica.—*Prize*—Mr. T. Ball. *Certificates*—Mr. Brown, Mr. Bullock.

Surgery.—*Prize*—Mr. R. E. Price. *Certificate*—Mr. Finnimore.

Midwifery.—*Prize*—Mr. R. E. Price. *Certificate*—Mr. V. Jones.

Practical Midwifery.—*Prize*, (for a report of 700 cases attended,) Mr. T. S. Gundry. *Certificate*—Mr. Gatliffe.

Summer Session.

Medical Jurisprudence.—*Prize*—Mr. R. E. Price, *Certificate*—Mr. Turner.

Botany.—*Prize*—Mr. R. E. Price. *Certificates*—Mr. Bullock, Mr. Turner.

Practical Chemistry.—*Prize*—Mr. H. Brown. *Certificates*—Mr. W. Bloxam, Mr. Price.

Clinical Surgery.—*Prize*—Mr. Allen. *Certificate*—Mr. Finnimore. This prize is offered by the Lecturers of this school and is open to competition to all Students entering to the hospital practice.

Mr. Lane then, in behalf of his colleagues and the students, in a very neat and highly eulogistic speech, requested Dr. Pettigrew's acceptance of a portrait and lithograph, in testimony of their respect

and attachment to him as a friend, and one of the Lecturers upon anatomy and physiology. Mr. T. B. Phillips, a student, at the request of his fellow pupils, also made an address upon the occasion. Sir James Clark then presented the portrait, and Dr. Pettigrew, who was highly gratified, replied in an appropriate manner. Votes of thanks were then given to Professor Fergusson and the Chairman, and the proceedings terminated highly to the satisfaction of all parties.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on the 5th instant:—G. J. Thurston; J. W. Davidson; L. T. Cumberbatch; J. H. Boughton; A. C. Sydenham; G. Withered; W. Benham; A. R. Benson; H. R. D. Marratt; J. J. Parrish.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, April 27th, 1848:—William Cox, Bridgend, Glamorganshire; Andrew M'Lellan, Liverpool; Edward Andrews, Rainham; William Fuller, Piccadilly; James White Money, Fareham; Thomas Veem, Payhembury, Devon; Charles Drew, Okehampton; Joseph Alfred Bean, Reldon, Essex.

Thursday, May 4th, 1848:—Francis Yeates Jones; Robert Twemlow Spark, Newcastle-under-Lyne; Joseph King, Lewes; Henry Coleman, Dover; Wm. Edward Jeffereys, Guernsey; Alexander Somers, Thame; Thomas Thrush Frankland, Northallerton; William Hyde Cooke, Stockton, Worcestershire.

OBITUARY.

Died, April 15th, at Sorel, aged 28, Leon Gauthier, M.D.

April 23rd, at Girvan, of fever, Andrew Robertson, M.D.

April 24th, suddenly, at Bewdley, in the 80th year of his age, Edmund Whitcombe, Esq., of Hollyfast, near Cleobury Mortimer, in which town he had been for upwards of forty-two years in practice as a surgeon, prior to which he was ten years surgeon in the Honourable East India Company's service.

April 27th, at Philipsburg, Canada, aged 46, H. N. May, M.D.

April 29th, of fever, Mr. Richard Stephenson, Apothecary to the Cork Street Fever Hospital, Dublin.

April 30th, at St. Servan, France, aged 84, John Hayne Newton, Esq., M.R.C.S., and of H.M. forces.

April 30th, aged 42, Edward Duncan, Esq., Surgeon, Leadenhall Street.

May 3rd, in Upper Portland Place, Wandsworth Road, aged 38, William Squin, Esq., Surgeon.

Lately, at Hollymount, of fever, H. Gardiner, Esq., Medical Attendant of the Kilmaine Dispensary.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNIVERSARY MEETING.

The time for holding the Anniversary at Taunton is not yet finally fixed; but the meeting will probably be appointed for Wednesday, August 9th, and Thursday, August 10th, should these days suit the convenience of the Taunton Members.

NOTICE TO MEMBERS.

Gentlemen who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due, either to the Secretary of the District in which they reside, or to the Treasurer or Secretary of the Association.

ROBERT J. N. STREETEN, Secretary.

TO CORRESPONDENTS.

Communications have been received from Mr. T. Hunt; Mr. Crompton; Mr. Nunneley; Dr. Cotton; Mr. Martin; Mr. E. W. Day.

Mr. Boult will perceive that his request has been attended to.

It is requested that all letters and communications be sent to Dr. Streeten, Foregate Street, Worcester. Parcels and books for review may be addressed to the Editor of the Provincial Medical and Surgical Journal, care of Mr. Churchill, Princes Street, Soho.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

REMARKS ON THE PRESENT ASPECT OF MEDICINE.*

By W. Newnham, Esq., Farnham.

We are not prepared to say that much of the practice in the present day is not mere guess-work, especially with those who see their patients perhaps but once, or at all events, at very distant intervals; who have no opportunity of watching the influence of their medicines, and modifying that influence according to the peculiar state of the constitution, and rectifying the mistakes or imperfect knowledge of to-day, by the enlarged knowledge of to-morrow, and by the close observation of disease. We believe that a physician, in order to be a successful practitioner, and to carry out his plans, and to develope the agencies of medicine, should be a close attendant upon his patient; and where he is not so, we are not surprised at his hesitating to employ active measures, and at his trusting more to the *do-nothing* system of regimen (because it will do no harm,) rather than to the *do-something* system of medicine, over the influence of which he bears no regulating control; but this again is an error of the system of administration, and detracts not from the power of medicine.

Now, as to the influence of "Young Physic" in correcting these errors, and in working out the projected reformation, we have no means of judging of his powers. So far as parentage is concerned, since *fortes creantur fortibus*, we ought to expect much good from his future Herculean labours; but since we do find sometimes that children differ essentially from the direct parent stock, and are influenced by some previous bend sinister in the family escutcheon, we cannot yet rely upon what may be his developed powers. We cannot but recollect that he has not yet passed through the disorders and the trials of infancy; and we cannot yet predicate that his system will not receive so severe a shock from some of these trials as to enfeeble his progress towards maturity,—to stunt his powers,—to destroy his fair proportions,—and finally, to make him a puny man instead of a giant. Neither can we be assured that his associations will always be of the purest description, and that he will not be tempted in some evil day by some of the alluring provocations of society, to spend his strength upon unworthy objects, and to exhaust his powers upon very inferior pursuits, instead of upon that great and high destiny which the early breathings of parental vows would have placed before him. Therefore, we must indulge in hope, and cherish the heroic virtue of patience, in waiting for the development of the young champion's powers; and in the meantime, while we entirely concur with many of the educational precepts placed before him, we shall venture an observation or two upon some of the agenda, in order, if possible, to add our mite of contribution towards the realization of this *beau idéal* of perfection.

I. (1.) The preceding observations will have already explained our views with regard to the natural history of disease. To endeavour to obtain a deeper insight into the natural course and events of disorder in all its Protean forms by more care, more zeal, more industry, more nightly study, and more daily toil in the use of every legitimate means within our reach, is good and praiseworthy; but to obtain this knowledge at the expense of our patient is exquisitely cruel, and most deeply criminal. It is at once conceded that all organic disease and functional disorder of the system may have originated from some injury antecedently sustained, often from very remote causes, and frequently from the effort of nature to restore that which was wrong, or by the want of power to produce that effort. In either case, nature generally requires assistance,—in the former, to keep within due bounds that effort, which is almost always overdone,—and in the latter, to restore and re-animate her powers, and aid her in the accomplishment of her sanatory views. Left to herself, in both cases disorganization frequently results, and the physician has the uncomfortable reflection of the destruction of life by his supineness.

II. (4.) We quite agree upon the importance of introducing a more philosophical and "accurate view of the relations of remedies to the animal economy, and to diseases," and we are quite sure that a greater amount of careful and diligent observation will have its reward; but how is this to dissociate the minds of practitioners from the *post hoc propter hoc* notion, especially when tested by the numerical method! A judicious mind sets off upon the investigation of disease and its remedies; it seeks to obtain first every possible theoretical acquaintance with the former and the latter, and thus armed with study, it seeks to verify its principles at the bed-side. Here disease and its symptoms are investigated carefully; the effect of remedies is *minutely watched*; and the result is noted. By degrees, mistakes are corrected, a better acquaintance with the actual forms of disorder is obtained, a juster

* Continued from page 257.

confidence in prescribing is acquired, and the practitioner expects that in certain forms of malady, certain effects will be produced by certain remedies, and very generally he is not disappointed in the result. Here, then, is the experienced physician; but how is this obtained by the numerical method, except by summing up the preponderating number of *post hocs*, and arriving at the identical conclusion of *propter hocs*. Not so, the injudicious practitioner who infers that a *red herring is good for a tailor, but not for a cobler*, because, when exhibited in the same form of malady, the one died, and the other recovered. The difference is this, that the one prescribes judiciously and upon sound principles, discriminates results, and finally arrives at *post hoc propter hoc* results; while the other prescribes empirically without knowledge or principle to guide him, and arrives at conclusions, not from the summing up of a large series of inductions, but from a very small number of trials; the one is rational, the other irrational; the one is principled, the other is destitute of principle; the one appeals to reason and common sense, the other is alien from both.

III. (5.) This is a dangerous position, for although the "*anceps remedium melius quam nullum*" may be a very unsafe axiom, if it be construed to mean that any remedy, however wild,—however extravagant,—however absurd,—is better than no remedy at all, then, indeed, leave nature's operations undisturbed; but the cases must be rare indeed where *no* indication to be fulfilled may be extracted from a careful perusal of the patient, and his constitutional peculiarities, and his present disturbances. And if the case be so rare as to form only an unusual exception to the general result, the adoption of the rule of doing nothing, because the issue of the remedy is doubtful, is really only taking up the old nurses' plea, of letting the patient die undisturbed, or, as they would say, "a natural death," rather than endeavour to save him,—leave him rather in the hands of nature, and of Providence, than to the tender mercies of the doctor. But, as philosophers, we may not be guided by old nurses' views; we cannot be justified in our conduct to our patient, if we see him destroying by disease, and leave him to his fate, while there remains even a remote prospect of advantage from the *anceps remedium*. We are bound to eschew the remedy chosen at hazard; we are equally bound to employ the remedy, which, under the most deplorable circumstances, offers a hope of advantage to the patient. How often has the judicious physician been blessed with a joy almost unspeakable, when he has seen patients recovering under persevering energy, from conditions in which nurses, friends, and even less sanguine medical men, had given up all for lost. How deep must be the remorse of him who feels that a life may have been sacrificed from want of energy on his part!

IV. (6, 12.) We dislike polypharmacy as much as it is possible, and we would never exhibit a remedy of any kind unless we had a scientific reason for so doing, and unless we were prepared to defend our method of treatment upon philosophical, though it may be *misapplied*, (because *mistaken*,) principles. We claim no exemption from the errors and short-sightedness of humanity, and we dislike, with intense aversion, the miserable system of *prescribing for symptoms*, and exhibiting a certain drug for this, and a certain other for that, symptom, and varying our prescription several times in the day, according to the urgency of some particular symptom; and therefore we quite agree in the importance of *simplicity*, but we do not attach the same meaning to the term as does "Young Physic." By the term simplicity of prescription, we mean that combination of medicine, which in our best and deliberate judgment, we think most suited to meet and supersede the morbid action, of which we have endeavoured to take a comprehensive view, in all its bearings, upon the organs and functions of the body,—that form of medicine which, according to its present effect upon the constitution, we are prepared to carry on or to modify, till we have obtained certain changes, which will also demand certain other remedies to be then chosen and selected; and in doing this, we should consider that we have pursued an "*intelligible*" process, and should thus have excluded all unnecessary and useless drugs. But in doing so, we confess that we should have had very little regard to what would prove agreeable to our patient; we should have first decided upon what would do him good; and then if we could have made the same palatable, without injury to our own inductions, we should have had no objection. In carrying out these views, we believe that we should have pursued a rational, scientific, and beneficial system. In effecting this too, we should have had no difficulty in rendering ourselves intelligible to friends, in explaining the malady before us, what were our indications of treatment,—indications which *we* were endeavouring to fulfil by medicine, and which *they* were to support and aid, by following out the regimenal directions which we were about to give, all of which would bear upon carrying out one great principle. All this would be really *simple*, but not according to the nomenclature of "Young Physic," which evidently intends to avoid *combination* in medicine. Nothing can be more erroneous; and it would be a mere waste of time and paper to prove that the efficacy of medicine is enhanced by judicious combination,—not by the juxta-position of incompatibles, but by throwing together agencies, which will all tend by various routes to the same result.

V. (7.) We are disposed to think the exertions of "Young Physic" in the department of hygiene far more limited than our author believes. We agree with him as to the truth of the trite proverb, that prevention is better than cure, and that he who succeeds in limiting the incursions of malady, achieves for himself a far higher honour than he who assists and directs nature in her efforts to control malady. But we are very sceptical as to the power which the medical philosopher possesses of effecting any great good in this way. Take for instance one ruthless malady, phthisis,—all our epidemical visitations,—all our specific diseases,—and what power do we possess of preventing them by any exertions of hygiene. Why are they present at one time and not at another? And how is it that when

present we seem to possess few means for preventing their extension, beyond the ordinary qualification of susceptibility and non-susceptibility? Even with ague, we may drain marshes, and we may seem to gather to ourselves the laurels of victory over disease; and yet even here I would ask, how is it that a few years ago ague was prevalent over the entire country, and in districts where it was never known before? How is it that in an undrained portion of my own neighbourhood, where formerly ague was exceedingly rife, and scarcely ever absent, not a case of ague has been known for many years? Again, what means have we of preventing fever, where famine and destitution have been the promoting causes? And finally, what power do we possess of exerting such an hygienic influence over our patients in health, as shall induce them to be careful, and attend to its preservation? We would not undervalue hygiene; let it have its proper place, let it be diligently studied, but do not suffer it to supersede its more manageable neighbour, medicine, judiciously directed to the relief of disordered function.

VI. (8 and 9.) We quite agree with our author that much good may be done by abandoning the heroic method of treatment, provided that it be not supplanted by that system of negative expectancy,—the mischievous arrangements of the "do-nothing" school, which will ever prove a refuge for the idle and the unthinking. Man will gladly do any thing rather than think, and any system which encourages his *inertia*, must be fatally injurious. Nevertheless we think, that by careful attention he will find the same effects are to be produced by milder means, as by vaunted calomel and heroics, and that by throwing his mind into their active employment, he can do much good to his patient. The promotion of this end is to be accomplished by his better acquaintance with foreign medical literature. But here again is a great difficulty: the language is not sufficiently known in general to be read and studied with comfort, and if so, every possible advantage is gone. This difficulty may indeed be obviated by a more enlarged attention to preliminary education; yet it must be confessed, that the knowledge of living languages acquired at school is generally most inadequate for practical purposes. While then we ask to abate the recklessness of fool-hardy prescriptions, let us also strive to stem the sluggish stream of equally criminal inertness, and strenuously at least attempt to steer "with steady helm, and well-bent sail," between these two great evils. So with regard to the specific diseases, we had thought that it was an established axiom, not to attempt to interrupt their progress, but merely to watch their advancement, to moderate nature's action where it was excessive, and to remedy the evils of any organ or function which may happen to become disturbed in their course. But what a wide field does this open for judicious interference, while it affords no room for negligence, or indolence, or apathy.

VII. (10 and 11.) We agree with the objects to be placed before the mental vision of "Young Physic" in so far as regards the spirit of the former *agendum*. We believe that mischief perpetually arises from administering powerful remedies in large doses; we believe that irreparable evils accrue from the *uncalled for* exhibition of purgatives; and that much injury is occasioned by this perturbing system, by this thoughtless administration of drastic poisons, which are not converted into valuable remedies by the mere Æsculapian touch; and we quite think that much reform is needed, especially in this department of medicine. But we must enter our solemn protest against the administration of feeble or powerless remedies prescribed *pro formâ*, for the satisfaction of the patient's mind. Prescribe honestly, or not at all; if there be an indication to accomplish, pursue it, and if not, give nothing; tell the patient honestly that he requires nothing, or that you are ignorant of what is good for him, or that you are too indolent to think of what might be useful; and let him then judge whether he would like to cast himself upon the tender mercies of such *vis inertiæ*, or whether he would prefer placing himself under the care of somebody less given to slumber in guilty apathy over the sorrows and the sufferings of mankind, and better disposed to adopt the motto, "*Invenium viam aut faciam.*"

VIII. We agree that a "very elegant prescriber is seldom a great physician," and for the most obvious reason—he thinks very little of the good of his patient, but simply what will please his palate and amuse his mind; therefore it is that the patron of inertness becomes the elegant prescriber, because he grasps the shadow and throws away the substance. There are great errors in the present day, and in the present style of prescription; and much as we abhor the system of being paid for medicine,—much as we think it odious and intolerable, there are advantages even in this system which are forfeited by others. The honest practitioner is only anxious for the good of his patient, and selects the best medicines careless of their cost, because (if you please,) it is his interest to do so; while should he prescribe, and send his prescription to a druggist, who lives from the profit he can make upon his drugs, and who cares not how adulterated may be the medicines, because he has no interest in their effect, why the whole thing proceeds badly. And again, it is the fashion with many physicians of the present day, to prescribe medicine in a very concentrated form, of which a few drops, or a teaspoonful is to be taken in water or some simple vehicle. No accuracy can be obtained in this way, while teaspoons and tablespoons differ exceedingly in their size,—while one patient fills his quantity by a different measure from another,—while one takes a quantity of water and another a very little,—and while one drops for himself, and another trusts this agency to a friend. From this latter I have known death produced by a blunder made in the careless exhibition of prussic acid in drops.

IX. (13.) One word upon *mercury!* We believe that the use of this remedy is often inordinate—often misplaced—often mischievous. We have been saturated *usque ad nauseam*, by the public and by medical consultants, with the reference of every form of gastric and intestinal malady to bilious derangement; and that too, as a direct consequence of some primary irritation of the liver. We have been grieved with the

eternal and mischief-making prescription of calomel, and blue pill, and grey powder, for ever and aye, upon occasions where mercury in every form should have been religiously withheld; and we believe that the occasions for its exhibition are really *rare*. But we fully believe that when these occasions present themselves, no other medicine can advantageously and thoroughly supply the place of mercury judiciously administered. The fault is not in the remedy: it consists in the fact that its great curative powers have been demonstrated, and then by those who have little experience, or little thought, or little reason, it has been given without discrimination. The evil therefore consists in the mode of its administration; and the just method will not be learned by the advocates of the do-nothing system. Let us here again mention the great value of foreign medical literature on the subject of diseases of the liver, and their treatment without mercury.

X. (14.) But we cannot go with our author in his contrast between the "natural system of curing diseases, in contra-distinction to the pharmaceutical, or empirical drug plan, generally prevalent." We are quite willing to admit that in general we may be too little attentive to diet, regimen, &c., and that medicine loses much of its power by being deprived of the aid thus afforded. But we must deny the terms of the proposition—a very strict regimen for an omnivorous animal is equally repugnant to nature as the exhibition of medicine; there is just as much physiological license in the prescription of appropriate medicine, as of appropriate diet; a certain effect is to be produced upon the system,—slowly by diet, more rapidly by medicine; more securely, more thoroughly, more certainly, by diet and medicine combined. Hence, however, it will follow, that there will be just as much *empiricism* in the diet as in the medicine: the same effect is to be produced. If, then, medicine or diet be prescribed upon just *principles*, there is no empiricism in either; if they are prescribed without sufficient reason, and a sufficient knowledge of the object to be accomplished, then both are prescribed empirically. In fact the object of both is the same,—both are prescribed medicinally; if the one be required, so is the other; if the one be useful, so is the other; if the one be exhibited without sufficient thought, so is the other, and both are valueless. But the attempt to supplant medicine by diet, is to supersede the greater by the less, the prime agent by the adjuvant, to trifle with science, to discard its advantages, to despise its offers of mercy, and therefore "hygienic, regimenal, and external means" are to be rendered *subservient* to medicine; and in the order of nature and of society, the servant is not to change places with his master.

XI. We quite agree with Dr. Forbes in his suggestions (15. 16. 17.) for the promotion of professional science, and for taking enlarged views of malady, and for not treating disease by a name, but by looking especially after all the organs and functions of the body which may be disordered by its presence; but we cannot do so in his view of the necessity (18.) of "endeavouring to enlighten the public as to the actual powers of medicines, with a view to reconciling them to simpler and milder plans of treatment." We would make no secret of physic, at least, with the better informed part of the community who could understand our explanations; we would form our own opinions upon the existence of disorder, and we would give the reasons for that opinion, and the objects which we proposed in the treatment, and the way in which medicine and diet were to be brought to bear upon the fulfilment of these indications; and we would be prepared to answer honestly any questions which might be propounded. But to discuss the powers of the medicine we proposed to give, or to give a name to the disorder we were called to treat, we would carefully avoid, because we should only furnish our patient with materials for consulting various works of popular medicine or encyclopædias as soon as we had gone; we should have set their minds afloat; we should have destroyed their confidence in the plans prescribed by the very means which are so deprecated in practical medicine by the blight of *insufficient knowledge*; the natural effect of medicine would be impaired, and our object would be lost. This is not a theoretical opinion, but one which has been formed by painfully purchased experience, and we are quite sure that while we would treat our patients as men of sense, if we value their well-being and desire their recovery, we must not attempt to make them physicians. Much evil perpetually results from carrying our explanations even too far, or from endeavouring to force them into a mental calibre incapable of receiving them.

We thoroughly approve of endeavouring to impress upon patients the necessity for the treatment of disease in its earliest stages, but we submit that this recommendation is in direct opposition to that natural history of disease, which it is the primary object of our author to inculcate. Treat disorder early, ere yet habit shall have established it in the system of constitutional actions, or organic changes shall have taken place in the tissues, and the result will generally be successful; but leave disorder to develop its natural history, structural disease will be the consequence, and in vain will any treatment be adopted.

Most devoutly do we wish for the day, when all medical practitioners shall be paid for their time and talents, and not by the amount of medicine which has been exhibited; but this object is not easy of accomplishment with a large proportion of the community. In our own circle, with a certain class of patients, the payment by visits has been cheerfully and willingly adopted; and after a long series of years, we find that these patients have taken by far the most medicine, for two obvious reasons; first, that *they* knowing they did not pay for their *medicine*, took it unhesitatingly as prescribed; and, secondly, that *we* have felt no scruples in sending them as much as we thought desirable for them, and were not always seeking to spare their pockets. But with another large class of patients we have found it impossible to establish a payment for visits; they have fancied themselves imposed upon;—that visits were made for the sake of making a charge;—that they had not their *quid pro quo*, if medicine were sent in a concentrated form;—and that in fact

nothing would do but the old payment of so much per bottle. We have already stated our reasons for wishing that the present system may continue, not for own sake, but for the health and welfare of her Majesty's lieges.

And now we turn to a few observations of what strikes us as at this time especially wanting in the profession. Were we to take up this subject as it ought to be treated, in all its length and breadth, we should write a volume instead of an article; we shall content ourselves with a rapid glance at only a few particulars.

With regard to futurity, the great panacea to be recommended is enlarged preliminary education,—not simply relating to that which is professional,—not simply relating to that which is necessary to constitute the gentleman,—but by a happy combination of the two, to form at once the gentleman, and the medical man;—to teach him to *think*, to *reason*, and to *read*. In order to accomplish these objects, he must make a certain proficiency in mathematical study, and he must be acquainted not merely with the dead, but especially with the living, languages,—above all, with French and German; and these not learned as school-taught,—to translate miserably with the aid of a Dictionary,—but to read and understand thoroughly without adventitious aid. It is absurd to expect man to reason correctly, if he has never been taught the use of reason; it is absurd for him to talk of being acquainted with his profession, if he be not thoroughly imbued with an intimate knowledge of French and German. Nothing more shrivels and contracts the mind into the narrowest selfishness, than the impression that knowledge is to be found only within the circle of its own country.

Second only to this grievous mischief is that want of exertion, and of intellectual expansion, which confines professional reading almost exclusively to the *Journals* of the day. We have the highest possible respect for many of these Journals, and we believe them capable of much usefulness, but we also believe them effective of much evil, where they are taken as substitutes for more laborious research; as if the digested food of certain individuals could afford a proper supply of nourishment, if removed into the stomach of another. We look with much jealousy upon all these Journals and Retrospects, because they form a royal road to knowledge, and are to spare the trouble of research, and take the place of individual study. By means of these fugitive papers, prejudices may be sown, but opinions are not formed; the reasoning powers are never called into exercise, and a reference to a retrospect takes the place of research, and of really deep abiding thought. Tell me not that persons in actual practice have no time for reading; they have time enough if they will make it; what is wanting is inclination. After a weary day, a nap of fifteen or twenty minutes, and a dish of tea, will enable the brain to pursue its studies for hours, and almost every man may obtain time for study, if he will systematically improve it. But if he gossip all the morning,—if he return home to dinner and subsequent siesta of two hours,—and leave work to be done late in the day,—then, indeed he may not have time. But this arises from his own thriftless expenditure. We repeat it,—everybody has time for study if he will diligently improve the passing hours, and if he will redeem some portion of that time which is now devoted to little domestic luxuries, and to a larger allowance of sleep than is absolutely required. It may be said that the rule is too stringent, and that the common comforts of life are interfered with. Agreed: so it is; the life of a medical man must be a life of self-denial. But what are these little animal enjoyments when compared with the life and health of the poorest, and the meanest, and the most obscure of the family of man; what are they when contrasted with the unspeakable luxury of ministering to the wants, and weaknesses, and the infirmities of our fellow creatures? Who can estimate the delight which fills and animates the bosom of the medical attendant when he sees his plans succeed, and witnesses the gradual restoration to health and comfort of some valuable life, over which he has watched with intense anxiety. And although, under these circumstances, he may too frequently be assailed by ingratitude,—even then, he can fall back upon the consciousness of his own deservings, instead of that remorseful upbraiding which ought always to rest upon the heart of him who has not done his utmost to enlarge the boundaries of his knowledge, and to perfect the means for its application.

(To be continued.)

ON THE NON-ABSORBTION OF NARCOTIC POISONS BY THE LYMPHATICS.

By E. Welby Day, M.R.C.S., Resident Medical Tutor at Queen's College, Birmingham.

Before the discovery of lymphatic vessels, the power of absorbing was attributed solely to the veins; after this discovery solely to the lymphatics. Further investigation showed that absorption is effected through the agency of both systems of vessels, but that lymphatics absorb more slowly than veins, and that some substances are not taken up at all by them.

Thus the extended observations of Tiedemann and Gmelin led these authors to conclude that lymphatic vessels readily take up saline, but reject colouring matters—a conclusion which has been generally accepted by physiologists.

The later researches of Herbst (*a*) have shown that the absorbing power of the lymphatics is by no means so limited as has been commonly supposed, but that almost all soluble bodies may be conveyed into the system by these vessels. This is proved by careful experiment for alkaline and metallic salts, starch, colouring and odorous matters. There is, however, one class of bodies—those poisons which act on the brain and spinal system, and which are usually included under the term "narcotics," of which it is proved by

(*a*) Das Lymphgefasssystem und seine Verrichtungen, Gotting. 1844.

the most decisive experiments, that they cannot, under any circumstances, be carried into the system by the lymphatics. The fact has been long observed, but until recently, no sufficient attempt has been made to explain the anomaly.

Emmert (*b*) tied the abdominal aorta of a dog, and into a wound of one foot introduced ferrocyanide of potassium, into a similar wound of the other decoction of nux vomica. The ferrocyanide was absorbed and detected in the urine, but the nux vomica produced no poisonous effects. In another experiment, after tying the abdominal aorta, Emmert introduced prussic acid into a wound of the foot; after the lapse of seventy hours, no poisonous effects having presented themselves, the ligature was loosened, when symptoms of poisoning were observed in half an hour.

These experiments were confirmed by Schnell (*c*) and Schabel (*d*). Ségalas (*e*) after tying the blood-vessels of a loop of intestine, and injecting half a drachm of solution of extract of nux vomica, observed no sign of poisoning after the lapse of an hour.

Opposed to these facts, we have an experiment by the Academy of Medicine, of Philadelphia. After tying the vena portæ, nux vomica was injected into a loop of intestine; tetanus and death ensued in twenty-three minutes. Of this experiment it may be remarked, that it has been repeated by Mr. Blake (*f*) with opposite results, and that admitting the accuracy of the observation, it cannot be allowed that the poison was absorbed by the lacteals, for the communications which exist between the veins of the intestine and those to the vena cava (*g*), enable us to account otherwise for the result (*h*).

The experiments above quoted, together with those to be presently adduced, establish the fact that when the circulation through a part has been interrupted, a narcotic poison introduced does not exert its specific action on the system.

To account for the non-occurrence of poisoning under these circumstances, we are compelled to allow the truth of one of three propositions. 1st. The poison is altered and rendered inert in the lymphatics. 2nd. It cannot enter them. 3rd. Having entered, it cannot be conveyed by them.

The first proposition expresses the views of Emmert, Schnell, Weber, and Müller, but is opposed to facts (*i*). The second supposes such a difference in structure between lymphatics and veins, that by the same process (endosmosis,) by which fluids enter veins, they cannot permeate the coats of lymphatics—a difference which has not been ascertained. The third proposition states the opinion of Henle, an opinion at which he arrived on hypothetical grounds, but which will be found strongly supported by direct experiment.

Assuming to be true what has been rendered highly probable by physiological observations, that the motion of the lymph is effected through contractions of the lymphatics (*k*), it must be granted that the contractile power of these vessels being destroyed, all motion within them must cease.

On this assumption Henle bases his hypothesis; he conceives that, like other fluids, narcotic poisons are taken up by the lymphatics, according to the general laws of permeation and imbibition, but that the poisons, acting on the coats of these vessels, destroy their irritability, and incapacitate them from conveying their contents (*l*).

This hypothesis appears sufficiently plausible. The topical application of opium to the intestines destroys their peristaltic action. Aconite, infusion of tobacco, and other narcotic poisons, when absorbed from a wound, and carried by the circulation to the heart, paralyse this organ, and render it unable to contract on its contents. Finally, it can be shown that lymphatics, placed under the influence of a narcotic poison, are disabled from conveying into the system not only the poisonous agent, but also inert solutions, which, under normal conditions, they absorb with facility.

The following experiments were undertaken by Dr. Behr, at Henle's request:— (*m*)

Having confirmed the statement of Emmert that, when the circulation through the lower extremities is interrupted, ferrocyanide of potassium is readily absorbed from the one, whilst strychnia applied to the other causes no symptom of poisoning. Dr. Behr proceeded to ascertain the effect of introducing the poison and the salt into *the same* extremity.

The abdominal aorta was tied below the origin of the renal arteries; into a wound of one of the hinder extremities was then introduced a mixture of 100 drops of solution of strychnia, with 120 drops of solution of ferrocyanide of potassium. After the lapse of two hours and a half, no symptoms of poisoning having appeared, the animal was killed, and the bladder removed. Neither in the urine, on the walls of the bladder, in the peritoneum, in the blood within the

heart, nor in the ureters, could a trace of the ferrocyanide be detected. The thoracic duct was uninjured, and the aorta accurately tied.

In six similar experiments, Behr obtained evidence of the absorption of the ferrocyanide in only two. In one of these it was detected in the ureter, but was absent from the bladder; in the other a trace was found in the urine contained in the bladder. In neither were there symptoms of poisoning.

Behr attributes the absorption of the trace of ferrocyanide found in these two cases to neglect of precautions necessary to ensure that the solutions should not be conveyed into the system by the veins. These experiments appear sufficiently conclusive, and, if confirmed and extended to other poisons of the same class, would have established Henle's hypothesis. They have been repeated by Bischoff, of Giessen, with, however, totally opposite results (*n*).

Of two dogs, Bischoff tied the abdominal aorta, and into a wound of one thigh introduced solution of strychnia; into a similar wound of the opposite limb, solution of ferrocyanide of potassium. The first animal exhibiting no signs of the action of the poison, after an hour and three quarters, was killed. On testing with chloride of iron, the urine gave a dense blue precipitate, (einen starken blauen Neiderschlag.) This observation agrees with those of Emmert and Behr.

The second animal, showing no symptoms of poisoning, after two hours and three quarters, a further quantity of the solution of strychnia was applied to the same wound. In half an hour convulsions arose, which gradually proceeded to tetanus, of which the animal died about an hour and a half from the second application. In this case also the presence of the ferrocyanide in the urine was distinctly shown.

In two other dogs, Bischoff applied a ligature to the aorta, and introduced into *the same* wound the solutions of ferrocyanide of potassium and strychnia. In one case, after the lapse of an hour and three quarters, no symptoms of poisoning had appeared. In the other, indications of the action of the poison were observed in half an hour, and the animal died of tetanus in an hour and a quarter. In both, ferrocyanide was found in the urine; in the latter case, in the thoracic duct, but not in the blood.

From these experiments Bischoff concludes that, as readily as other soluble matters, narcotic poisons may be taken up and conveyed into the system by the lymphatics, a conclusion which, as we shall have occasion to show, is not altogether warranted.

The importance attached to all questions which relate to the action of poisons on the organism, is sufficiently attested by the attention this subject has received from physiologists. The point attempted to be established in this paper is invested with additional interest, since it would contribute to throw light on the motive power of the lymphatics, respecting which we possess so little definite knowledge.

The physiological importance of the question at issue, and the conflicting statements of those who had endeavoured to solve it, appearing to call for further researches, I had recourse to the following experiments, in which, under every precaution, I exposed to the absorbing power of lymphatics in the normal condition, and under the influence of a poison, two salts, both known to be readily absorbed by these vessels, and both susceptible of ready recognition in the secretions:—

(*Exp.* 1.) The abdominal aorta of a middle-sized dog was tied below the origin of the renal arteries. Into a wound of the right hind extremity, near the foot, was now introduced ninety drops of a saturated solution of acetate of strychnia, followed by one hundred and twenty drops of a solution of iodide of potassium, (in the proportions of one drachm of iodide to one ounce of water.) Into a similar wound of the opposite limb were introduced one hundred and twenty drops of a solution of ferrocyanide of potassium of the same proportions. After the lapse of two hours and a half, no symptoms of poisoning having appeared, sixty drops of the solution of strychnia were dropped into the wound in the abdomen. In ten minutes convulsions ensued, and the animal died tetanic. The bladder was removed, and the small quantity of urine contained in it received into a test tube. On the addition of a drop of solution of persulphate of iron, there at once appeared a bulky precipitate of Prussian blue, which presented a greenish hue, owing to the deep yellow colour of the urine. The fluid was filtered, the precipitate washed, and to the filtrate was added a few drops of chlorine water, followed by solution of starch. No change became apparent.

(*Exp.* 2.) The abdominal aorta of a dog was tied. To a wound of the right hind foot was applied a mixture of thirty drops of hydrocyanic acid, (containing about 40 per cent. of anhydrous acid,) with one hundred and twenty drops of solution of ferrocyanide of potassium. Into the opposite limb were introduced one hundred and twenty drops of solution of sulphocyanide of potassium, (containing one drachm in one ounce of water.) No sign of the action of the poison having appeared in two hours and a quarter, the animal was killed by introducing into the wound of the abdomen ten drops of the acid. The bladder was removed and the urine received into a test tube containing a few drops of solution of persulphate of iron. It immediately assumed a blood-red tint, but underwent no further change. To the fluid was now added a little sulphuric acid, and after the subsidence of a slight effervescence which ensued, a slip of pure zinc was introduced. In the gas which was evolved sulphuretted hydrogen could be distinctly recognized by the odour, and a slip of lead paper was blackened by it. The fluid had now lost its red colour.

(*Exp.* 3.) A third experiment was conducted in a similar manner. Into the right hind foot was introduced a mixture of one hundred and twenty drops of solution of sulphocyanide of potassium, with forty

(*n*) I have made a brief abstract of Bischoff's experiments, from his paper in Henle und Pfeufer's "Zeitschrift für rationelle Medizin." Band iv., Heft j., p. 62.

drops of prussic acid; into the opposite limb one hundred and twenty drops of solution of ferrocyanide of potassium. After the lapse of an hour and three quarters, the animal having shown no indication of the action of the poison, was killed almost instantaneously by introducing into the wound of the abdomen a few drops of the prussic acid. The urine was received into a tube containing solution of persulphate of iron. A distinct blue deposit left no doubt of the presence of ferrocyanide, whilst the unaltered colour of the supernatant fluid indicated the absence of the sulphocyanide.

These experiments were sufficient to satisfy me of the correctness of the observations of Emmert and Behr. Nor, on examination, do the experiments of Bischoff prove so convincingly opposed in their results as, at first glance, may appear the case.

In Bischoff's first experiment, after an hour and three quarters, sufficient ferrocyanide of potassium had been absorbed to give a *strong* precipitate of Prussian blue when tested for in the urine, yet the strychnia exposed to the same absorbing power gave no evidence of its action on the system.

Again, an objection applies to Bischoff's experiments which does not lie against those of Behr and myself; the solutions were applied to the upper and inner part of the thigh, where a collateral circulation may be quickly established by anastomosis, and the poison carried into the system by the veins. Several circumstances in the detail of these experiments seem to point to this objection.

Thus, in the second experiment, the application of thirty to forty drops of a strong solution of strychnia produced no effect in two hours and three quarters, by which time the collateral circulation must be pretty well established; a *second* application of the same quantity *now* brings on symptoms of poisoning in half an hour—exactly the same time, be it observed, in which in the fourth experiment a single application of this quantity of poison brought on tetanus.

From the experiments which have been recorded, we may, I think, justly conclude—1. That strychnia and prussic acid cannot be conveyed into the system by the lymphatics. 2. That the non-absorption of these poisons is due to a specific action exerted by them on the coats of the lymphatics, by which the irritability of these vessels is destroyed, and they are rendered incapable of transmitting their contents.

From the dissimilarity in the operation of strychnia and prussic acid, it may be reasonably inferred, that most other poisons belonging to the same class will, on investigation, be found to conduct themselves in the same manner towards lymphatic vessels.

PERFORATING ULCER OF THE COLON: MECHANICAL OCCLUSION BY HARDENED FÆCES.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Conceiving that the annexed case offers pathological peculiarities sufficient to merit for it a place in the Journal, I beg to present it for your acceptance and obliging insertion.

I am, Sir,
Your obedient servant,
CHARLES ANDERTON.

Leigh, near Manchester,
May 23, 1848.

I was called to visit Miss H. J. S——, aged 11 years, in September, 1847, labouring under an attack of measles, which, prior to my being called in were well and fully developed, but at this particular juncture a retrocession of the eruption had taken place without any special indications of mischief. After the lapse of a short time evident symptoms of abdominal lesion made their appearance, indicated by strong and almost uncontrollable paroxysms of pain. In addition, we had in this case, the rectum charged to an amazing extent with fæcal concretions, resembling masses of calcareous earth, which my enfeebled little patient could not, *per vires naturales*, part with; they therefore required to be removed manually with a kind of scoop, and this, indeed, required much force. I ought to observe that, when the more hardened portions had been removed, the throwing up of an injection had the effect of encouraging the bowels to relieve themselves, and the motions were invariably of the most massy character, both in point of consistence as well as quantity, notwithstanding the extremely attenuated and wasted state of the child. This condition of matters continued unceasingly, with the abdominal paroxysms encreasing in frequency and severity, notwithstanding large doses of opiates, until death, on the 16th instant, happily terminated her earthly sufferings.

The *post-mortem* appearances were as follows:—The body externally wasted to the most extreme degree, with a dry, harsh, and scabrous condition of the entire integuments; the latter over the abdomen of a dark leaden colour, with considerable distension from flatus; internally the peritoneum inseparably adherent throughout to the abdominal parietes; the mesentery uniformly and thickly studded with enlarged glands, and darkened from congestion; the folds of the intestines had become strongly knitted together by adhesive inflammation throughout their whole course. At the sigmoid flexure of the colon, *a large perforating ulcer*, of the diameter of a shilling, was discovered: this portion of the bowel, with the rectum, was enormously distended with fæcal matter, of the character above noticed. Remarkable to relate, the whole superior course of the bowels was devoid of solid matter, but considerably inflated; the internal lining of the colon was studded with small circular ulcers; the liver of a

dark carbonaceous colour, and greatly diminished in size; bladder empty and contracted.

It is my opinion that, owing to the distended state of the lower part of the colon and rectum, life was preserved, and the fatal event protracted, from the strong mechanical occlusion of the morbid opening, by the indurated fæces, preventing thereby fæcal effusion into the abdominal cavity.

OPERATIONS ON THE LIPS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

Through our much improved Journal, I would offer to the profession a suggestion or two for operations upon the lips, which, though not very important, seem likely to be acceptable, from their frequent applicability, the facilities they afford to the operator at the time, and satisfaction in the result.

In excisions, the hand of an assistant at each angle of the mouth, to compress the arteries, is often considerably in the way, and may be better employed. I have therefore, on the last fifteen or twenty occasions, applied, at each extremity of the lip to be operated upon, a strong and large pair of Dieffenbach's forceps, which have effectually controlled the hæmorrhage, and left the hands of the assistant at liberty for other purposes. I have even operated without other assistance than that of the forceps. Their concave margin is towards the ear, and after applying, it is well to give them a slight pinch, to increase the compressing force. Messrs. Weiss and Co. have made them for me, and know the size and strength required.

Another trifling suggestion is the adoption of thin steel pins, instead of the usual silver ones, cutting off the points with pliers, as in operations upon the saphena.

The only other innovation I have to recommend upon the operation, is one I have practised for many years, in imitation of the veterinary mode of producing compression and co-aptation after phlebotomy,—namely, the use of strips of lint, twisted about the pins, instead of thin ligatures. The lint should be of the firm kind, called "endless," and the strip about half an inch wide. Its value lies, of course, in the wider and more serviceable compression it gives; indeed, by two pins, with lint applied to each in a crossed form once, then two or three times tightly coiled round at the base, and tied, the whole incision is occupied, extended compression given, and the dressing completed. The lints being soaked in blood during their application, will even adhere, after careful removal of the pins, until cicatrization is perfect.

I remain, Sir,
Your obedient servant,
THOMAS PAGET.

Leicester, May 15, 1848.

CASES FROM PRIVATE PRACTICE.*

By John Richard Wardell, M.D., Edin.;
Late President of the Royal Physical and Hunterian Medical Societies, Assistant Pathologist in the Royal Infirmary, Edinburgh, &c. &c.

Case VII.

Fits during Labour.

Remarks.—In offering the following remarks upon the foregoing case, it may firstly be observed, that the nomenclature employed, must needs appear to obstetricians and systematic writers less precise and definite than could have been wished; but it unfortunately happens both for those who write and their readers, that the multifarious aspects which diseases assume, their complications and the many contingent circumstances by which their ostensible phenomena are modified, that it is often no easy matter, nay, frequently very difficult, or even impossible, to refer them to the defined classes of nosological arrangements. Sometimes it is true we meet with diseases in a simple and perfectly intelligible form, when we can with confidence speak explicitly as to their real nature, but as asserted, it is often otherwise, as in the illustration now presented to the reader, in which there were certain negative and positive facts, which in my own mind, rendered it doubtful whether the case could or could not be considered as one of puerperal convulsions,—that is according to the generally received notions of the term, unless we receive the subdivisions of certain authors who have made a classification of it during the puerperal state, some of which classes describe the affection as very different to others. It was under this incertitude that I have employed the appellation as above.

Such other cases of puerperal convulsions as have come under my notice, and were real puerperal convulsions of an alarming character, are in many respects diverse to the one described here. In the former the muscular agitation was much greater, there was tossing about of the head, biting of the tongue, foaming at the mouth, stertor, a full strong, labouring pulse, and heat of surface; in the latter, as we have seen, there was no foaming, a quiescent rigidity more than a convulsive action of the muscular system, no rattling during respiration, a cold surface, small slow and compressible pulse, with lachrymation, dilated pupils, etc., rendering the symptoms of a highly hysterical nature. "Dewees," says Ramsbotham in a foot-note in his work, "classes puerperal convulsions under three heads—epileptic, apoplectic, and hysteric Baudeloque arranges them under the titles of tetanus, epilepsy, and catalepsy. Merriman styles them dystocia epileptica; while Velpeau and Desormeau prefer the general term eclampsia." The first paroxysm was perhaps somewhat more of a convulsive character than those which followed, most probably owing to the

* Continued from page 263.

greater irritation given to the system by the continued efforts of expulsion, and speaking from my limited experience of what I have observed in the grave forms of the affection, the attacks coming on after the birth of the child, were less severe than those previous to delivery, a fact which I believe as a general rule holds good.

Those who have seen much of the diseases of females are aware that we sometimes see hysteria and epilepsy combined, there being indubitable characteristics of each affection, inextricably blended, and in the instance of this girl, a review of the case must needs convince the reader that the symptoms of hysteria were considerably mixed up with her affection. I now, though several years have passed away, recollect an instance of the kind which occurred in the wards of the Edinburgh Infirmary, during the time that I was clinical clerk to the late Professor Graham. It was a true compound of hysteria and epilepsy, so much so as to render it a matter of considerable doubt as to which of the names could most properly be adopted. In the case-book of the hospital I had described it as more particularly being considered epilepsy; the Professor, however, at his visit, said that although it very nearly simulated that form in several features, it laid an equal claim to Protean hysteria. It is cases like these which throw out insuperable difficulties to systematizers and medical commentators, that preclude exactitude of opinion as to diagnostic conclusions, and often render treatment at least but doubtful. It would indeed be Utopian to suppose that our art will ever become so far perfected, as to completely clear away all these and many kindred difficulties which so mystify the science of medicine; yet it is to be hoped that a narrow scrutiny of the phenomena of disease—the greater attention which is now generally paid to cause rather than effect—and the more philosophical notions which obtain in the schools, and in the profession in general, will ultimately tend in an important manner to ensure results, whereby our notions will become of a definite character, and consequently with more clearness, point out the mode of cure.

Referring to the above report of the case, we see that the os uteri, with an unaccustomed suddenness, (in a primiparous female,) became dilated. The first fit was just at the time when the os was about to acquire its full expansion, immediately before the termination of the first stage,—a circumstance worthy of some notice, as all obstetric writers agree that puerperal fits by far more commonly supervene, shortly before the entire dilatation of the womb, and which is previously mentioned when remarking upon the instance of Ann W———, in No. III. of this series. Again, the parts being so cool, did not lead to the supposition that any untoward event would occur. The pelvic outlet was not by any means contracted, the presentation was natural, the pains came on at regular intervals, the patient did not complain of any head affection, and altogether it was fair to pronounce that the delivery would be one of the most favourable description.

The reader, on returning to Case No. III. will, in the observations there offered, find that certain authorities have considered the causes of puerperal convulsions as divisible into centric and excentric,—that is, certain morbid conditions existing in the brain and spinal marrow themselves, or a source of irritation applied to the sentient nervous extremities, which irritative impression would of course be conveyed to the central organs by the afferent nerves properly so called. Now, in this instance, the bowels had long been irregular; a week before parturition there had been considerable constipation, and we are distinctly told in the report, that at the time of her delivery there was diarrhœa, a condition undoubtedly that was calculated to act as an excitant; and when we also take into account the long disordered state of the bowels, the irritative matters thus collected;—also that this was an illegitimate birth—that it was a first birth—that the consciousness of error, the loss of self respect, forfeiting perhaps the friendship and esteem of friends by which the mind could not fail to become in some degree perturbated; there were physical and moral causes, calculated to disorder the nervous system, and thus constitute a first cause, for the development of this kind of affection.

Professor Simpson has recently given to the profession some new views relative to the radical pathology of puerperal convulsions, but certain of the conclusions at which he has arrived appear invested with some degree of doubt, nor can such be implicitly received before more extensive data have been amassed elucidatory of the subject. Medical facts, as they are termed, ought ever to be tardily accepted, and not before ample corroborations have been made by others, or there would be a danger of new doctrines, and those blended with error, being subscribed to, to the prejudice of more confirmed, though opposed, opinions. It is true that a vitiated condition of the blood, which disease of the kidneys must in some measure produce, might by disordering the system generally predispose to the affection in question; but it might be asked why should the convulsions become manifest precisely at the time of parturition, seeing that the cause had been long existent? Why not as likely before or afterwards? Again, convulsions *do* supervene when not the slightest disease of the kidneys is present, not even functional disorder. In the instance of the girl Shaffell, (if we are to consider her's as a mild modification of puerperal convulsions,) the urine upon being carefully tested was in a perfectly healthy condition. The inquination of the blood which Dr. Simpson opines as the manner in which the nervous system becomes

disordered, and thus rendered in a state highly predisponent to convulsive action, must be from the absorption of urea, a salt which in health passes off in the urine, and which possesses those deleterious effete matters that are positively poisonous, and cannot be retained in the circulation without exerting a noxious influence upon the entire animal economy, and if continued must needs usher in a fatal termination. Now, "in several specimens of the blood of patients suffering under severe puerperal convulsions, furnished by Dr. Simpson to Dr. Christison and Dr. Douglas Maclagan, these gentlemen had been *unable* to detect any traces of urea," which of course supplies a negative fact, casting doubt upon Dr. Simpson's theory. I have but little dubiousness in my own mind, that death in typhus fever in many cases is positively poisoning by the presence of urea in the blood, and that if the proper remedies had been used many a life might have been saved. I will not here, however, enter into the details of that theory, which has been freely discussed in another place;* yet this may be said, that in those instances which I have seen all but lost, when ureal symptoms were recognized, and afterwards the salt produced abundantly from the blood, convulsions were not the prominent symptoms—the condition of narcotism was present, and the effects produced were those of a general depression of vital power. Albuminuria, it is true, by creating a general disorder in the body, might make convulsions in some measure liable to come on, but to say that it constitutes a specific cause, is still dubious, nor can that conclusion, although emanating from so respectable an authority, be yet implicitly adopted. It cannot be denied that the most frequent ascertainable causes of puerperal convulsions are constituted by extrinsic irritation, as that produced by dyspepsia, affections of the liver, the accumulation of scybalous and acrid matters in the bowels, disease of the digestive mucous surface, of the uterus or its appendages, mobility of the nervous system, and a depressed condition of the mind.

If the reader will compare this case with No. III., he will see that the symptoms of the one demanded a line of treatment differing from that of the other. In the instance of Ann W——, active and copious depletion was without any hesitation the rational mode of procedure, and indeed this is indisputable when it is considered that in her case fifty ounces of blood were drawn, with the most signal benefit within three hours. But let us ask, what were the conditions demanding such energy? There was a hot skin, violent convulsive agitation, with a pulse large, quick, labouring, and strong; the eyes looked fierce and starting, and from the intense facial congestion the brain was manifestly in a state of considerable congestion. With Shaffell were very opposite states; the surface was cool, even below par; the pulse, though immediately after the supervention of the first fit of tolerable strength, rapidly became small, weak, slow, and compressible; the facial congestion was less formidable; in fine, her case was one indicating stimulation, one in which the vital powers required rousing, and such the treatment fully verified. In the treatment of Ann W——, I was from a full conviction of its efficacy led to lay much stress upon the prompt and very fearless use of the lancet; and in another instance, if the same phenomena were present, I should undoubtedly observe the same mode of cure; but to have done the same in the instance of Shaffell, would have been acting in opposition to scientific as well as common sense principles, nor could such have possibly been attended with any felicitous results. It is these complicating conditions in diseases of apparently a similar nature that cast such incertitude on the line of cure to be pursued, and that can only be determined upon at the moment when our aid is required. Trite rules in medicine can never with safety be in a undeviating manner observed, and we must rather base our measures upon deductive inferences, founded upon general principles, than blindly adhere to the trammels of the schoolmen.

The great use of the voltaic electricity in this case was extremely manifest, and it may confidently be asserted, that this remedy will every day come more into general use. Its virtues in many cases, particularly in nervous diseases, are beyond dispute, and have long been acknowledged, though not employed to that extent, which as a medicinal measure with advantage it might have been. Though an agent of inanimate nature, philosophical investigations have abundantly proved that the so-called nervous influence is in many appreciable characteristics precisely similar; hence, when the nervous influence in our bodies is deficient or impaired, to supply this agent appears rational and philosophic. We have seen that in this case its application by rousing the central organs was immediately followed by the most perceptible effect produced in the vascular system, and that with such effect the unfavourable symptoms were removed.

Straton Villa, Acacia Road, Regent's Park.

Hospital Reports.

WEST NORFOLK AND LYNN HOSPITAL.

COMPLICATED SURGICAL CASES UNDER THE CARE OF CHARLES COTTON, ESQ., M.D., F.R.C.S.,

RESECTION OF THE ELBOW: SUBSEQUENT AMPUTATION OF THE UPPER ARM.

Isabella Bolton, aged 24 years, admitted February 7th, 1847, with disease of left elbow, of twelve months' standing. Had two years before been a patient in the hospital for disease of the same joint, which yielded

to constitutional treatment, and Scott's plan. She complains of frequently-occurring torturing pains in the shoulder and hand, and the least movement of the limb causes insufferable distress. The fore-arm is semi-flexed and fixed, and the joint ends of the elbow bones are considerably enlarged.

February 25th. Excision of the deceased parts having been sanctioned in consultation, the patient was brought into the operating room, and seated in a chair, in the presence of most of the medical gentlemen in the town and neighbourhood, who attended to witness the operation, and *the use of æther-inhalation.* The influence of æther being speedily and completely induced, and kept up by causing the patient to inhale the vapour at intervals. Mr. Cotton, sitting behind and grasping firmly the fore-arm with the left hand, proceeded to make, with a strong scalpel, an incision about three inches in length, on the ulnar side of the back of the elbow, in the direction of the limb, and by a bold cut from outer to inner condyle, falling into the middle of it at right angles, penetrated the articulation. The flaps were then dissected back, and the ligamentous and muscular connections (much disorganized,) further detached, by cutting close upon the bones. The ulnar nerve, imbedded in greatly degenerated soft parts, was turned over the inner condyle. The ends of the bones were now protruded, and being deeply damaged by caries, the entire removal of their articular extremities was determined upon, and quickly effected, by applying the saw, (the soft parts being guarded by a copper spatula,) to the end of the humerus, and afterwards to the olecranon, and continuing the sawing through the head of the ulna, that of the radius being removed by the cutting forceps. Three freely-bleeding vessels were secured by ligatures, and the flaps brought in apposition by sutures. The patient, *who throughout did not betray the least evidence of pain or knowledge of the operation,* sobbed hysterically on the withdrawal of the æther, and when removed to bed vomited, and complained much of its depressing and nauseating effects. The arm was raised and supported semi-flexed upon a pillow, covered with oil silk, and left exposed.

Vespere.—Considerable oozing of blood from the wound, which was directed to be kept constantly wetted with a strong infusion of matico. Liq. Opii Sedativi, m. xx., ex aqua statim sumend.

26th. Passed a good night; the hæmorrhage ceased only on applying a bandage moistened with the matico. Repetatur haustus hora somni.

27th. Had an excellent night; slight redness about the fore-arm and wrist, and a sense of tightness at the elbow.

March 1st. Feverish and uneasy; bowels unmoved; pain and throbbing at the elbow. Capiat Potassæ Citratis, dr. j., actu effervescentis ad libitum. Bandage and sutures removed; some sanio-purulent fluid came away. Water dressing.

3rd. Bowels acted freely after taking a draught of senna and rhubarb; feels very comfortable. Full diet. Limb placed upon a clean pillow.

11th. Going on well; removed to another bed, the one adjoining her being occupied by a patient suffering from erysipelas.

19th. Wound granulating kindly, and discharging freely. Forearm placed upon a padded splint, semi-flexed, and suspended by a string. Allowed to sit up.

21st. Arm uneasy. To remain in bed, and keep it quiet upon a pillow, which she prefers to the splint.

March 28th. Leathern splint and bandage applied; arm rather uneasy; feels something of the old pain down the forearm and wrist.

April 5th. Prefers resting the limb on a pillow; splint removed.

15th. Wound considerably diminished and healed.

26th. A light jointed splint of steel and leather applied. The limb admits of slight passive flexion, without much pain or inconvenience. Can grasp the thumb, index and middle fingers, and retain anything put within the hand. No power over the ring and little fingers.

May 2nd. No power over the limb or improvement in the motions of the hand; allows passive flexion freely with less pain; dislikes the splint.

8th. Complains of the old pain, and despairs of regaining any use in the arm. The wound is nearly healed, a small discharging outlet only remaining, surrounded by sluggish granulations of thickened callous tissue. Ordered to practice the hand and flex the elbow occasionally, and to be made an out-patient.

July 7th. Returned to the hospital. There has been gradual wasting of the limb, and constant pain, which now extends from the elbow to the shoulder, chest, and back; entire loss of mobility; the hand has a peculiar purple-like and shining appearance; the thumb is contracted towards the palm, and the fingers fixed over it; elbow admits of passive flexion, giving great pain; desires to have the arm removed; wishes the operation had been performed at first, though much obliged for the means used to save it. To remain quiet for a time and await a consultation.

26th. Upper arm amputated at the centre, by antero-posterior flaps; great vascularitity, five ligatures required. Æther inhaled; had no recollection of the operation, although she moaned much during its performance, and afterwards felt great sinking and distress at the stomach, became pallid and very sick. Ordered a teaspoonful of brandy to be repeated a few times, at intervals.

Vespere. Depressing effects of the æther continuing, with occasional attempts to vomit. R. Potassæ Bicarb., gr. x.; Ammon. Carb., gr. iij.; Liquor Opii, m. xx.; Aquæ, oz. iss. Fiat haustus cum Acido Citricii, gr. x. in impetu effervescentis sumendus.

27th. Slept three hours during the night; nausea continues. R. Acid. Nitr. Dil., m. xv.; Aq. dest., oz. ij. Fiat haustus, quarta quaque hora capiend in effervescentia, cum Potassæ Citr., dr. ss.

28th. System much ruffled, and tongue white and furred; pulse quick; skin hot; bowels unmoved; phlebitic appearance of the stump, redness extending to the shoulder; dark sanious discharge. Sutures and isinglass plaster removed; parts to remain exposed.

R. Liq. Ammon. Acet., oz. iss.; Magnes. Sulph.,

dr. vj.; Sol. Ant. Tartr., dr, iij; Syr. Papav., dr. iij.; Aq. ad Oss. M. Sumat oz. j. statim. Repetat. dosis omni tertia hora donec alv. responderit.

29th. Bowels moved; sympathetic fever abated; stump looking better. Perstet in usu Misturæ bis terve in die.

August 2nd. Redness altogether disappearing; stump granulating and healthy looking. Ordered chop and porter daily.

10th. Stump nearly healed, some pain in shoulder.

17th. Neuralgic pain still in the limb and shoulder. Adibeatur Emplast. Lyttæ parvum inter scapulas.

25th. No pain since the application of the blister; stump quite healed; feels perfectly well. To be supplied with a small blister or two to apply in case of any return of pain, and to be discharged.*

Morbid appearances of the amputated limb.—Inspection made July 28th, in the presence of Dr. Ingle and other gentlemen. All the structures around the elbow consolidated; a fistulous passage from a small posterior subcutaneous abscess led to the head of the ulna; tendinous attachment of the biceps to tubercle of the radius undisturbed; brachialis anticus converted into a tawny yellowish tough fascial structure, adherent to the ulna, lined by the synovial membrane, and forming in front the capsule of the joint; triceps tendon firmly attached posteriorly; the median and radial nerves in the region of the elbow appeared larger than natural, as did *the ulnar nerve, upon which, about an inch apart, were found two bulbous expansions, the size of horse beans*; the ends of the bones, tolerably compact in structure, and but little enlarged, were strongly connected together by direct and oblique fibres of ligamentous tissue, presenting several points undergoing cartilaginous and bony transformation; soft parts of the forearm and hand pale and atrophied. A preparation is preserved of the elbow.

Remarks.—The limited circumstances of the patient, and considerations whether a shortened and stiffened limb might not prove of less service than the adaptation of an artificial one after amputation, alone contra-indicated excision. The general health appeared good, age favourable, and the pain and distress to have only a local origin; the reported results of similar operations, too, were highly encouraging, and the use of æther-inhalation disarmed of importance any objections which might be urged on the ground of pain and tediousness of the operation. Nothing at first could exceed the well-doing and progress of the case, and the inspection of the parts afterwards removed, showed how admirably nature meets such emergencies; granulations proceeded quickly but soundly to fill up the wound, the disease seemed to expend itself in a free discharge, daily becoming more healthy, and partial motion of the hand was allowed, without much inconvenience. This desirable state of matters did not, however, prove of lasting duration; in less than five months a return of pain, (sympathetic neuralgia, and hyperæsthesia, showing permanent, local, or centric morbid impression,) together with the wasted and useless state of the limb, now an incumbrance, obliged the patient again to present herself at the hospital, and to beg that the arm might be amputated.

The failure of the operation of excision seems justly attributable to the advanced stage of disease of the joint ends of the bones, destroying, secondarily, the muscles, &c., and seriously involving the nerves. An error was, most probably, committed in the endeavour to preserve the mobility of the elbow, instead of securing absolute rest and *utmost proximity* of bone surfaces, to favour the deposition of callus, and bring about close union by anchylosis, hard or soft, particularly as the degenerated state of the muscular structure observed at the time of the operation gave but little hope of its peculiar irritability, and contractile power being likely to be retained or regained.

* This patient shortly after became an in-patient of the hospital, being *lame* from the knee being swollen and encrusted with large impetiginous scabs; from this she recovered. She is now, and has been some time, an out-patient, complaining of anomalous and obstinate neuralgic pains and hysterical troubles, affecting "principally the shoulder and side upon which she was operated."

PROVINCIAL
Medical & Surgical Journal.

WEDNESDAY, MAY 31, 1848.

The Registrar General's Return of Mortality for the Quarter ending March 31st, presents, as usual, important subjects for reflection. The mortality is still greatly above the standard, and though not quite so high as during the preceding December quarter, it exceeds that of any other of the March quarters, during the ten years for which these returns have been calculated. The actual mortality of the 117 districts included in this return amounts to 57,710, or 6,755 above the calculated number; that of the corresponding quarter of last year (the year of famine,) was 56,195 or 6,027 above the calculated number. So that although the actual mortality of the quarter is somewhat less than that of the December quarter, in which the deaths amounted to 57,925, we fear that, considering the comparative mildness of the season, there are some special cases of fatal disease still in operation beyond the fluctuation of the ordinary atmospheric conditions.

"In London the mortality," it is stated, "was high during the first five weeks of the present year. In the week ending February 5th, 1453 deaths were returned exclusive of deaths by violence, and sudden deaths; in the next week the deaths were 1296; the temperature rose, and in the week ending February 19th, the deaths were 1102; in the five following weeks the deaths only varied from 1090 in the first, to

1054 in the last week but one of the quarter ending April 1st." The causes of this mortality would seem to be chiefly amongst the zymotic diseases, which were "more than twice as fatal in 1848 as they were in 1847." The deaths ascribed to influenza during the thirteen weeks were 102, 102, 89, 56, 59, 47, 27, 33, 18, 11, 10, 16, 8.

A similar excess in the mortality prevailed in the provincial districts, taken collectively; typhus, scarlet fever, hooping cough, and small-pox would seem to have been epidemic in several parts of the country. With regard to the mortality from the last of these, for which the simplest means of prevention are in the power of all, the subjoined extract evidences a neglect almost criminal:—"The extent to which vaccination is neglected in some parts of the county is deplorable and inconceivable. Such facts as the following are, it is to be feared, not uncommon in other districts besides East Sunderland. 'Deaths 140, considerably above the average; 69 more than in the corresponding quarter of last year. The increase is principally to be attributed to the prevalence of small-pox in the district. *Forty-seven persons have died of small-pox, (only one after vaccination.)* Out of the 140 deaths 84 are under 5 years.' Here 47 persons, chiefly children, died; and this implies that some hundreds besides were injured and disfigured, by a disease that may be almost altogether prevented by vaccination; which the legislature, under the administration of the Poor-law, has placed within the reach of every poor child in the kingdom."

We understand that an alteration has been introduced into the Public Health Bill, under the pretence of preventing unqualified persons from being appointed officers of health, which may cause serious inconvenience to the public service, and in the existing circumstances of the medical profession, be made the grounds of much annoyance and injustice to some of its best qualified members. The alteration referred to is the substitution of the words "a legally-qualified medical practitioner," for "a member of the medical profession," the effect of which would probably be to exclude all but members of the College of Physicians of London, and the Society of Apothecaries from holding any medical office under the Bill. The Government have, we believe, no wish of the kind, but it behoves all who may feel themselves interested in the question, immediately to represent the effect of the alteration to Lord Morpeth, and to point out to him the injurious consequences which cannot fail to result in some of our provincial towns, and especially in the northern counties. If we are not mistaken, an eminent and most energetic sanitary officer residing in an important seaport town, whose unwearied exertions in the cause of the public health are acknowledged by all, and who has made great personal sacrifices to this object, might thus be rendered incapable of holding that office, which he now occupies so much to the benefit of his fellow townsmen.

The judgment given by Mr. Justice Coleridge in the case of Dr. Berncastle and the Croydon Jury, expresses so decided opinion on the illegality of the conduct of the Jury, that although technically the redress sought for was unavoidably refused, the verdict may be said to have been virtually quashed. The following are the observations of the Learned Judge:—

An application had been made for a *certiorari* to bring up the coroner's inquisition held on the body of Elizabeth Hopkins, for the purpose of its being quashed or traversed. His Lordship, having recapitulated the facts as stated upon moving the rule, and which were then fully reported, proceeded to say, that a coroner's inquisition was held on the body of the woman, and it was stated that a good deal of feeling had existed: much evidence had been offered, and reflections had been made upon Dr. Berncastle, who had appeared before the coroner, and had offered to produce evidence, but the coroner had refused to allow it; and ultimately the jury found a verdict, "that Elizabeth Hopkins had died from exhaustion from protracted labour, and that Dr. Berncastle had shown the greatest inhumanity in leaving her, and they thought him unfit to remain as a medical officer of the Union." Under these circumstances, the application had been made to bring up the inquisition for the purpose of quashing it. Of course an application of that sort could only be made where it was stated that there was some defect upon the face of the inquisition, or some material fact which it was desired to traverse. It was suggested that the verdict tended to reflect unjustly on Dr. Berncastle; it was not suggested that any defect otherwise was apparent on the inquisition, that made it necessary to consider whether the part objected to was relevant at all, and whether it could be considered as part of the finding of the jury, because if it was not a part of the finding, then there was a case in point which had already been decided, when the Court refused to interfere. Here it appeared to him that the jury had exceeded their jurisdiction. They were empanelled to inquire into the cause of the death; they found the cause of death to be exhaustion, but they did not say, and no doubt they had plenty of disposition to say it, that

Dr. Berncastle's conduct had anything to do with it; but the jury went on gratuitously to make accusations against him. He was obliged to say that this application could not be granted. He would not dismiss the rule without expressing regret for so doing, because he felt that great injustice had been done by the jury. He said great injustice, without pronouncing an opinion as to what Dr. Berncastle's conduct had been in that respect. They had taken upon themselves without authority to pronounce an opinion reflecting upon Dr. Berncastle's character, and there had been absolute injustice in the result, because the guardians had dismissed him from his employment in consequence of that, and without having heard that gentleman or his witnesses in his defence; and it was much to be regretted that the coroner had taken down the statement the jury had made. They were empannelled for a particular purpose; but they had no more authority to express an opinion on Dr. Berncastle's conduct than on his (the learned judge's) or any other person who had nothing to do with the matter. They had no right to make that expression, and the coroner had done wrong in taking it down, especially after he had refused to allow Dr. Berncastle to be examined, or to hear his witnesses. There was abundance of evidence by medical gentlemen in the affidavit, of important matter, to show that Dr. Berncastle's conduct had nothing to do with the death; and upon the whole, with regret, it appeared to him that the rule must be refused.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

Continuation of Mr. Crompton's Digest of the Depositions on Burns and Scalds, made at inquests held before James Chapman, Esq., Coroner for the Borough of Manchester.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death.	Parts which were burnt.	How the accident occurred.	Remarks.
			1840				
41	F.	9 yrs.	Jan. 12	16 hours	Not mentioned	Her clothes caught fire in lifting a panful of water off the fire	She was alone. Linseed oil & lime water
42	F.	6 yrs.	Jan. 14	14 hrs.	All over the body except the feet	Holding her frock to the fire to dry	No one in the house, except another child four years old.
43	F.	66 yrs.	Jan. 24	3 days	Neck, head, & ears	Her cap and shawl caught fire, but it is not known how	It appears that she was of weak mind
44	F.	2 yrs.	——	2½ hrs.	"Burnt like a cinder"	The mother had gone to fetch her husband from the public-house, leaving her two children alone in the house, the eldest being only 4 years old. The younger one's clothes caught fire from lighting paper	The eldest child's pinafore was on fire, and this child would have been burnt likewise if a neighbour had not entered at the time and put out the flames.
45	F.	3 yrs.	Jan. 30	30 hrs.	Left side, left hand & arm, back, left leg, and pudenda	Mother in bed. A boy 10 years old, who had kindled the fire, left the poker in it to make it burn. When red hot the poker fell from the fire, and set this little girl's night-gown on fire as she sat before the fire upon the hearth	
46	M.	10 mths	Jan. 28	5 days	Abdomen, and apparently all the front of the trunk, from the neck to the legs	A little boy of 6 years of age, had him in his lap, and upset some boiling coffee upon him	Lime water and linseed oil.
			1839				
47	F.	3 yrs.	Dec. 9	56 days	Back, both arms, neck, head, & shoulders. In stripping the child, the skin came off the neck with the string of the pinafore	Mother, and the woman to whom the mother had entrusted her child, both absent. Does not appear how the clothes got on fire	Infirmary.
			1840				
48	M.	4 yrs.	Feb. 10	2 days	Neck, right arm, face and right side	His pinafore caught fire when standing upon the fender	Mother out waiting. Had left 4 children by themselves in the house, the eldest being not more than ten years old.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death	Parts which were burnt.	How the accident occurred.	Remarks.
			1839				
49	F.	46 yrs.	Dec. 1	74 days	Left arm, left side, & breast	The corner of her shawl took fire while standing at the fire. A drunkard	Infirmary.
			1840				
50	F.	1¼ yrs.	Feb. 13	24 hrs.	Bottom, legs, and face	The child was left alone in the house for a few minutes, sitting upon a table, upon which were a lighted candle, and some sewing. The child upset the candle upon the sewing	Linseed oil and lime water. Afterwards flour.
51	F.	7 yrs.	Feb. 14	7½ hrs.	Right hand & arm. Right side, face, & left arm	Her clothes caught fire in lifting the kettle off the fire. Mother gone out for potatoes. This girl and two younger children alone in the house	Oil and lime water were applied immediately and then the child was taken to the Infirmary.
52	M.	80 yrs.	Feb. 17	24 hrs.	Right arm, right side, right thigh and stomach	He upset the candle ubon his dress. "Infirm and helpless." Only children in the room with him. Time lost in putting out the flames	Infirmary.
53	F.	12 yrs.	Feb. 17	30 hrs.	All over her abdomen. Face & arms	Blowing the fire, when a spark fell upon her pinafore. No one in the house but two younger children. Mother gone out for potatoes	Infirmary.
54	F.	8½ yrs.	Feb. 23	20 hrs.	Right arm, & shoulder, chest & body	In taking a plate off a panful of porridge, her frock caught fire. Mother ill in bed	Oil was applied, and then she was taken to the Infirmary
55	M.	2 yrs.	Feb. 24	7 hours.	Both arms, chest, face and neck, thighs & right side	Mother had left the house for about seven minutes, on returning she met her child in flames	
56	M.	4 yrs.	Feb. 26	5 hours	All over the body except soles of his feet	Alone in his parents' cellar. Had been left in charge of his brother who is nine years old, but the latter had gone out before the accident occurred	Infirmary.
57	F.	10¼ ys.	Feb. 26	9 hours	All over except legs and feet	Supposed to have been blowing the fire with bellows. No one in the house but some young children	Infirmary.
58	M.	4 yrs.	Feb. 26	2½ hrs.	All over except his feet.	Not known how. Had been left alone in the house for a short time	Infirmary.
59	M.	9 yrs.	Mar. 3	13½ hrs.	All over his body	Pinafore caught fire in trying to reach up the chimney. No one in the room but his brother, six years old. Mother gone out for potatoes	Infirmary.
60	F.	4½ yrs.	Mar. 6	3 hours	Belly, breast, arms, & face	Not known. Left alone in the cellar. Father gone in search of work; mother at the factory	Infirmary.
61	M.	3¼ yrs.	Mar. 7	7 hours	Chest, arms, face	Clothing caught fire whilst the mother was up stairs dressing	Infirmary.
62	M.	50 yrs.	Feb. 24	13 hours	All over his body except left leg and head	When intoxicated he put a lighted pipe into his waistcoat pocket	Infirmary.
63	F.	9 yrs.	Mar. 9	32 hrs.	Left arm, chest, thighs, belly, and face	Not known how. Was in a neighbour's house, who left her down stairs for a few minutes whilst she went up stairs to give her husband some broth	Infirmary.
64	F.	7¾ yrs.	Mar. 10	15 hrs.	Arms, and all over her body, except her legs and feet	She was lighting the fire. Her father in bed. It does not appear whether her mother was living	Infirmary.
65	F.	19 yrs.	Feb. 24	14 days	Back, shoulders, right thigh, & left leg	A nurse. In lighting the nursery fire her dress caught	Infirmary.
66	M.	3 yrs.	Mar. 20	4 days	Right leg, left foot, & bottom	A drunken man upset a coffee kettle full of boiling water upon the child's legs	Linseed oil & lime-water.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death.	Parts which were burnt.	How the Accident occurred.	Remarks.
67	F.	10 yrs.	Mar. 24	7½ hrs.	All over the body	Her pinafore caught in stirring the fire	Infirmary.
68	F.	10 yrs.	Mar. 24	1 hour	Body, arms, neck & face	Mother had left for a few minutes the room in which they lived. How the child caught fire is not known	Infirmary.
69	F.	4 yrs.	Mar. 24	9 hours.	Legs, breast, arms, & face	Her parents left her alone in the house; on their return they found her in flames upon their bed, *the bed, too, being on fire.* It does not appear how the child got on fire. She was left down stairs by the fire-side nursing her doll, and they had told her before they went out not to touch the fire	Infirmary.
70	F.	6 yrs.	Mar. 28	11 hrs.	All over her body, except her legs	She and another child of 4 years of age were left alone in a cellar, whilst the mother went out to sell eggs. The neighbours found a box in the cellar on fire. It does not appear how the accident happened	Infirmary.
71	F.	8 yrs.	Mar. 28	13 hrs.	All over her body except her legs	Her mother left her alone by the kitchen fire mending her stocking whilst she went out to buy some food. On her return the child was found burnt	Infirmary.
72	F.	11½ ys.	Mar. 28	12 hrs.	All over her body	Mother gone to the bake-house, leaving the deceased by herself	Infirmary.
73	F.	32 yrs.	Mar. 24	18 days	Thighs, legs, & lower part of the back	She was smoking, and is supposed to have set herself on fire by means of her pipe	Infirmary.
74	M.	4½ yrs.	April 13	6 hrs.	Both arms, body, face, and back	Mother had left him with another child two years old alone in the house while she went across the yard. His pinafore took fire whilst boiling an egg in a saucepan	Infirmary.
75	F.	3 yrs.	Mar. 9	40 days	Shoulder and back of right arm	Mother out of the house, when a burning ember fell from between the bars of the grate upon the child, who was sitting near the fire	Mother applied treacle, and took the child to the Infirmary.
76	F.	3½ yrs.	April 16	18 hrs.	The mouth	She had been drinking from the spout of the kettle. Mother down stairs in another room	Under quacks. She could not swallow any medicine. Blisters were seen in the mouth.
77	M.	5½ yrs.	April 20	3 hours	Belly, breast, and legs	After being put to bed went down stairs and lighted paper at the kitchen fire. Parents had gone out to walk, and supposed that he was asleep	Infirmary.
78	M.	3¾ yrs.	April 20	4 days	Thighs and abdomen	A panful of boiling water left on the floor	Linseed oil and lime water applied by the parents. Afterwards taken to the Infirmary
79	F.	2½ yrs.	May 1	3 hours	All over her body except her feet	Left alone with another young child in the house. In reaching a jug from the mantel-piece her clothes caught fire	
80	F.	62 yrs.	April 29	8 days	Not specified	Supposed to have fallen upon the fire in a fit. Very infirm, and liable to dizziness	Infirmary.
81	F.	2 yrs.	May 5	36 hrs.	Right side of her face, arm, right side, & belly	Went into a neighbouring house in the absence of the female living there. Not known how she got on fire	Dispensary.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death.	Parts which were burnt.	How the Accident occurred.	Remarks.
82	F.	2 yrs.	May 12	41 hrs.	Mouth	Drinking boiling water from the kettle spout	Infirmary. No operation performed.
83	M.	7 yrs.	April 7	37 days	Both arms, the face, round the throat	His top went under the grate; in getting it out his pinafore caught fire. Was living with a sweep to whom his parents had given him up for the purpose of being trained as a sweep	Infirmary.
84	F.	3 yrs.	April 26	21 days	Face, right arm, breast	Lighting the lash of a whip. No one in the room with the children	At first under the Infirmary; afterwards under a druggist.
85	F.	23 yrs.	April 3	52 days	Arms, back, & right side	Sitting by the fire unwell, when a spark flew upon her clothes. No one in the house with her	Infirmary.
86	F.	21 yrs.	June 12	4 days	Face, neck, arms, chest	An idiot; subject to fits. Not known how she got on fire	Infirmary.
87	M.	1½ yr.	July 5	32 hrs.	Head & body	The mother had left some hot water upon a chair; he pulled over the vessel in which it was contained, and scalded himself. The mother was about to wash him	Infirmary.
88	M.	19 mos.	June 30	15 days	Thighs, legs, & belly	A pan of broth boiling on the fire tilted on one side, and the boiling broth fell upon him	Linseed oil & lime water. Goulard water.
89	F.	2 yrs.	July 13	5 days	Breast & stomach	Pulled over a jug of hot water upon herself	
90	F.	36 yrs.	July 10	10 days	Thighs, back, & right arm	Had been stooping to take some patchwork out of a basket with her back towards the fire, when her clothes caught	Infirmary. She could not speak so as to be understood, and was sensible for a few days only, after admission.
91	F.	4 yrs.	July 24	2 days	Breast, arms, ears & back	Mother had left her alone in the house. Discovered in flames by a neighbour	Infirmary.
92	F.	41 yrs.	Aug. 4	36 hrs.	All over her body	Cutting fire-wood, having a lighted candle on the floor near to her: her dress caught fire	Infirmary.
93	M.	5½ yrs.	Aug. 22	15 days	Both arms, right leg, and face	Supposed to have been lifting the kettle off the fire with his pinafore. No one in the room with him	Infirmary.
94	F.	1 yr.	Sept. 8	37 hrs.	Bottom of its belly & thighs	A *piece* came out of a jug full of hot coffee: the coffee flowed upon the child	Flour, then a lotion. (Convulsions.)
95	M.	23 ms.	Sept. 20	10 hrs.	Neck and head	The mother had left some hot soup upon the floor in a basin, the child fell off the sofa into it	Infirmary.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

March 6th, 1848.

FRANCIS ELKINGTON, Esq., in the Chair.

LARYNGITIS: ULCERS PERFORATING THE THYROID CARTILAGE.

Mr. Carter exhibited a preparation, illustrated by a drawing, of two ulcers of the larynx, perforating the thyroid cartilage, in a case of tubercular disease of the lungs.

A man, aged about 35, two years and a half ago had cough, with night perspiration. These symptoms left him for a few months, and then returned. Thirteen or fourteen months ago an abscess formed in front of the larynx, preceded by tickling in the throat. It was opened in three months, and seemed to heal in the course of a month, but a moisture continued to issue from the orifice, and a month before his death air began to pass out of the original opening. In a week or ten days afterwards, another opening formed in the integuments, above the original one, from which air passed so freely, as to interfere with articulation, and to require the patient to stop the orifices with his finger before he could speak. He died with all the symptoms of phthisis, in a fortnight after the second opening had been established. He was hoarse from an early period of the laryngeal disease. He denied having suffered from secondary symptoms of syphilis, although he had had gonorrhœa repeatedly. He was a man of very dissolute habits.

Post-mortem.—Tubercles were found in the lungs; the mucous membrane of the larynx was much thickened and rough, and completely separated from a large portion of the right wing of the thyroid cartilage; the

hollow thus formed communicated with the interior of the larynx by two ulcers, one large and ragged in the situation of the right ventricle, the other smaller, but able to allow a lead pencil to pass through it, situated lower down, smooth and round. The two wings of the thyroid cartilage were completely separated from each other along the pomum Adami; the exposed cartilages ossified and rough. The crico-thyroid ligament partially destroyed. The integuments were partially separated from the front of the thyroid cartilage, and were perforated in two places. The vocal cords of the larynx were destroyed on the right side, partially on the left. A portion of the surface of the thyroid cartilage was ossified both within and without the larynx, a greater extent of the internal than of the external surface.

NECROSIS OF THE TIBIA.

A tibia in a state of necrosis, in consequence of exposure of the bone by sloughing ulceration, was exhibited by Dr. Russell.

A man, aged 59, a patient of Mr. John Simons, had suffered from an ulcer of the right leg for many years; it healed several times, but again broke out, without, however, presenting any character different from that of a simple ulcer of the leg. He was taken into the infirmary, and whilst there the sore began to slough, and at the same time a like change took place in many other similar cases in the house. The tibia became extensively exposed, and separated from the surrounding parts. Amputation was performed. On examining the limb, a large sloughing ulcer occupied all the inner side of the leg; the tibia was almost isolated, and the periosteum separated from the bone. The bone was in a state of necrosis. When the tibia was sawn down, the fibrous layer was found thinner than natural, the cancellated structure dead, and the cancelli and medullary canal full of sanious pus. The lower extremity of the bone was quite healthy, as was the fibula; the ankle-joint also healthy.

SOFTENING OF THE SPINAL CORD: HYPERTROPHY OF THE HEART: GRANULAR KIDNEYS.

Dr. Fletcher exhibited the cervical portion of spinal cord softened, hypertrophied heart, and granular kidneys, from a man whose chief symptom was a remarkably slow pulse.

The patient was 58 years old; he was a mender of broken china, and never engaged in any more laborious employment than walking to collect his work. He had been under Dr. Fletcher for eight years, and had once been presented to the Society on account of a remarkably slow pulse. He was subject to attacks resembling asphyxia, in which he became giddy, and would be apt to fall. For these he was in the habit of being bled, with much relief. His most striking symptom was extreme slowness of pulse; it was often as low as twenty-five, and the patient reported it occasionally at ten beats in a minute. Dr. Fletcher had often met him accidentally, and had taken the opportunity to examine his pulse, but he never found it higher than thirty-two, the temperature of the surface of the body rather low. Dr. Fletcher could never detect any abnormal sound over the heart; the beat was very long, as though the heart dilated to as great an extent as possible, and then contracted briskly. In early life the man had suffered an injury to the back of the head, and he often complained of pain in the cervical region of the spine. Six months ago he manifested symptoms of consumption, of which he died, two months ago, and it was remarkable that when the phthisical symptoms were established, his pulse maintained a speed of 120 or 130, and the fits of asphyxia ceased to recur.

Post-mortem.—Nothing remarkable in the brain; atrophy and softening of the spinal cord opposite the lower part of the 4th, 5th, and 6th cervical vertebræ, equal in degree throughout the extent indicated. Heart hypertrophied; both ventricles filled with clots; some atheroma in the aorta, and aortic valves somewhat puckered; the other valves healthy; some patches of old lymph on the surface of the heart. Liver a little congested; kidneys granular; had passed albuminous urine during the latter part of his life. Dr. Fletcher stated particularly that there were no symptoms referrible to the spinal disease besides the local pain, the peculiar action of the heart, and the attacks simulating asphyxia, which doubtless depended on the state of the heart. These attacks, as stated, were always relieved by bleeding, and his pulse rose after the operation.

NARROWING OF THE DESCENDING COLON.

Dr. Fletcher related the following case:—The patient had been suffering some time from obscure symptoms of obstruction to the intestines; there was occasional swelling of the abdomen, which would subside, and vomiting. When Dr. Fletcher saw him, his abdomen was enlarged, particularly near the right hypochondrium; he was passing light-coloured fluid fæces rather abundantly. The fæcal discharge then ceased, and after a short time vomiting came on, and soon become stercoraceous, the matter ejected resembling that which had been passed by stool previously. This succession of symptoms recurred frequently. The abdomen was enlarged as stated; swollen generally, somewhat tympanitic, and elastic. On percussion, Dr. Fletcher also noticed a deep seated local fluctuation, extending from the ascending, to the termination of the transverse colon. This fluctuation occurring in one part only of the abdomen, Dr. Fletcher thinks a sign strongly indicative of obstruction in the colon. He had found it in two cases of obstructed colon, in which the fluctuation existed in the left side, indicating, as he thought, obstruction in the sigmoid flexure, and the result verified his diagnosis. In this case, as the fluctuation was not situated so low in the abdomen as it was in the cases referred to, he believed that the stricture was higher in the colon, and hence an operation would not afford any relief to the patient. The man was in good health excepting that he emaciated. He was treated by injections and other measures to open the bowels, and his food was carefully regulated. He grew thinner and at last died suddenly, greatly enfeebled by want of nourishment. The intestines were dilated in their whole extent up to the termination of the transverse portion of the colon, where the gut became greatly

contracted with thickened coats, and continued so as far as the anus. Other viscera healthy.

The fluctuation in these cases, Dr. Fletcher remarked, is not accompanied with dulness, as there is a considerable portion of air contained in the gut, in addition to the fæcal matter.

FOREIGN BODY IMPACTED IN THE RECTUM.

Dr. Fletcher exhibited a portion of a wooden skewer impacted in the rectum.

He was called in to a patient who was suffering from symptoms of fistula of the anus. There was swelling and inflammation, with pain and great tenderness about the anus. He suggested an examination of the bowel by the finger, when a portion of skewer, one inch long, was felt lying across the gut; this having been removed, all symptoms subsided. The patient could not explain the presence of the skewer.

Mr. Elkington alluded to a case of extreme tenesmus in a child, caused by the presence of an apple core in the rectum.

CHLOROFORM IN TRAUMATIC TETANUS.

A finger, amputated in consequence of injury, the patient recovering from tetanus on the administration of chloroform, was exhibited by Mr. R. L. Baker.

The ring finger having become engaged in some machinery, the first phalanx was torn off. On the second day the finger was a little swollen and painful; and there was slight pain in the epigastrium, and some nausea, after purging, &c. On the third day the symptoms were improved, but the finger was more swollen and painful; a scarlet rash broke out over the body, and his throat became sore, so that Mr. Baker thought it an attack of scarlatina. On the fourth day the hand was much inflamed, and the febrile symptoms increased. Leeches, fomentations, and salines. On the fifth day, after a bad night, during which he was supposed to be dying, at 8, a.m., Dr. Fletcher saw him, with Mr. Baker. He was found in a state of general tetanus. Tincture of hemp, and a turpentine clyster, were administered, and at noon, as he was no better, chloroform was tried; as the chloroform affected him, the muscles became gradually relaxed, and in five minutes, (having lost the power of articulation and of deglutition for the space of twelve hours,) he began to mutter, all the muscles of the body soon became quite relaxed, and he spoke intelligibly. Mr. Baker kept up the chloroform for three quarters af an hour, and then left his patient apparently sleeping quietly At 9, p.m., he found that in an hour after he had left him, he had come to himself, and had lost all tetanus. He continued to improve for eight days; at the end of that time, as there was a threatening of return of the tetanic symptoms, Mr. Barker amputated the finger, and the patient is now recovering rapidly.

CANCEROUS TUMOUR FROM THE CLITORIS.

Mr. F. Elkington exhibited a small cancerous tumour from the clitoris, and upper part of the right nympha.

A woman, aged 74. The tumour had been growing seven months. She had suffered much pain, with itching and burning. She was relieved for a time by various applications, but during the last month the tumour grew rapidly, and she became greatly distressed by it; the irritation of it caused diarrhœa; therefore, as she was in good health, the tumour was removed, and the whole right nympha and the clitoris with it. The surface of the tumour was ulcerated; it had the appearance of an excrescence from the clitoris, and upper part of the right nympha. The neighbouring glands were unaffected.

FIBRINOUS TUMOURS OF THE PLACENTA.

Mr. F. Elkington presented a placenta, containing some small tumours, apparently of fibrin.

A lady, confined with her first child, delicate, aged 30, was taken on the Saturday with pain, and was not visited till Sunday evening. The labour had not made much progress. Mr. Elkington observed that she looked remarkably pale, though there was no other symptom. He learnt that on the Friday preceding she had felt sick and faint. She was confined about five, on Monday morning; the child was putrid. After delivery the uterus remained so large, that Mr. Elkington suspected there might be a second child; soon the placenta came away, and immediately after it a large dark coagulum.

The placenta was studded with several small, firm, tumour-like bodies, about the size of a walnut, their outer surface pale, and looking as though ulcerated; their texture softish, and presenting the appearance of fibrin engaged in the placental tissue; most of them contained a cavity, partly filled with semifluid matter resembling altered blood. A coagulum adhered to the surface of the placenta when it came away. Mr. Elkington suspected that from the altered state of the placenta, a full supply of blood could not be obtained for the nourishment of the child, and that its death might be in part attributed to that circumstance.

Foreign Department.

ON INFLAMMATION, LIMITED TO THE SEROUS MEMBRANES OF THE VENTRICLES OF THE BRAIN, AND ITS TERMINATION IN CHRONIC HYDROCEPHALUS.

By M. Rilliet, of Geneva.

(Translated for the Provincial Medical and Surgical Journal.)

Acute inflammation is not always limited to the membranes of the surface of the brain, but sometimes invades the arachnoid which lines the ventricles. This combination of external and internal meningitis does not sensibly differ in its symptoms from peripheral meningitis alone, it remains to be seen whether the limitation of the disease to the ventricles is marked by any peculiar manifestations.

This question, however, is not easy of decision, as instances of uncombined ventricular arachnitis are exceedingly rare, and we should have left it without any attempt at its solution, had we not fortunately encountered a case which promises to throw some light upon the subject.

In both peripheral and ventricular meningitis, the disease originates during a state of perfect health, with headache, vomiting, constipation, and fever; but

in the peripheral form, the intelligence is disturbed at an early period, while in the other it may remain intact until the close of the disease. In the external meningitis of children of two or three years of age, convulsion is not a characteristic symptom; while, (judging from the single case narrated below,) it is an essential accompaniment of meningitis of the ventricles.

The case alluded to is as follows:—

A little girl, aged 6 years and a half, robust, with a well-developed chest, born of healthy parents, having been in perfect health the evening previously, awoke on the morning of the 7th of February with headache, and refused her breakfast; nevertheless she went to school as usual, but soon returned, on account of an increase of headache. She then went to bed and fell asleep, but vomited on awaking. The headache continued to increase, and she was quite unable to sit up. In the evening she was seen by M. Stroehlin, and was found to be complaining of headache, and intolerance of light and sound. The skin was dry, the pulse quick, and the tongue white. She vomited bilious matter abundantly, but there had been no relief from the bowels. The mental faculties were intact. Tartar emetic was exhibited, with the effect of inducing copious vomiting and a good bilious motion. The headache diminished, and the child fell into an unquiet sleep, during which she perspired profusely. At midnight she awoke and vomited again.

On the third day the vomiting had ceased, and the patient appeared in every respect better, but on the evening of the fourth day she was attacked again with violent headache, increase of fever, and tetanic convulsions, which continued through the night. In the intervals she slept restlessly, frequently crying out from the violence of the headache. Leeches and sinapisms were applied, and purgative doses of calomel given. It is unnecessary to follow the case through all its details. Suffice it to say, that on the eighteenth day the pulse became slow and irregular; on the twenty-first there was complete deafness. On the fifty-second day the intelligence was disturbed for the first time, and the convulsions became less frequent. On the sixty-eighth day idiotcy was complete, and at the end of four months the child died, after a renewal of severe convulsions.

Post-mortem.—The bones of the head were thin, but the sutures were not separated; the dura mater did not adhere to the cranium; the convolutions were flattened, and their interstices almost obliterated; the membranes on the surface of the brain, as well as of the base and medulla oblongata, were slightly opaque, and were detached with great facility; the sinuses were not unusually distended with blood.

On cutting into the lateral ventricles they were found to be distended with serum, the lining membrane being gelatinous in its entire extent; the central portions of the brain, so far from being softened as in acute hydrocephalus, were firmer than natural. There were neither tubercles nor granulations in any portion of the cerebral mass.

CLINICAL MEDICINE AND SURGERY IN THE CONTINENTAL HOSPITALS.

1. *Polydipsia.*—M. Rayer has lately had a female under his care, whose sole complaint was excessive thirst combined with an equivalent diuresis. Examination of the urine proved that it contained no sugar, and was in fact perfectly aqueous. Under these circumstances M. Rayer prescribed camphor in doses of six grains three times a day, by which a cure was effected in the space of two months.

Polydipsia is a malady, the pathology of which is at present unknown, and it is therefore necessary to have recourse to empirical treatment, as in the preceding case.

2. *Pneumonia and Chronic Ulcers.*—M. Rayer professes to have frequently noticed that patients who have been cured of old standing ulcers of the extremities, become the subjects of severe, and often fatal, pleuritis and pneumonia. Recently a case of this kind was observed by him in the person of an old soldier, who for twenty years had chronic ulcers with extensive eczematous inflammation of the legs. These suddenly dried up, and he was attacked with pneumonia. M. Rayer, in addition to tartar emetic internally, treated him by blisters to the seat of the former ulcerations. The vesications afforded marked relief.

3. *Burns treated with Ice.*—The cases which were alluded to in the "General Retrospect," (April 19th,) have all done well, no traces of cicatrization being left. All the injured surfaces were in fact, under the influence of the ice, covered with a thin pellicle which could only be distinguished from the surrounding integument by its slightly brownish tint.—*Annales de Thérapeutique.*

4. *Diseased Conditions of the Mitral Valve.*—Incompetency of this valve is generally accompanied by narrowing of the auriculo-ventricular orifice. The valvular lesion under consideration is not unfrequently accompanied by a pseudo-chlorotic state, distinguishable from true chlorosis by the concomitant enlargement of the spleen. In these cases the patients complain of pains in the shoulders, which, according to Jaksch, persist until the system is improved by the use of chalybeates. Jaksch mentions the cases of three individuals who, from early youth, had laboured under this affection of the valve, and in whom the phthisical constitution ultimately became developed. He attempts to explain the presumed connection between these diseases, by supposing defective nutrition, owing to the imperfect manner in which blood is propelled through the aorta.—*Hannoversche Annalen*, 1847. *Clinical Notes taken in the Hospital of Prague.*—From the *Monthly Journal*, May, 1848.

5. *Endocarditis.*—Depositions in the spleen almost always accompany endocarditis, and these correspond in character with the endocardial exudations, being purulent if the latter are purulent, and so on. Jaksch states, that the endocarditis following acute rheumatism, very frequently gives rise to pyæmia. That the formation of aneurism may sometimes be induced, when the

texture of the heart has been weakened by carditis or endocarditis, appears evident from the details of a case, in which inflammatory exudation on the lining membrane of this organ co-existed with inflammatory softening of its whole structure at the apex, and in which, at this point, a considerable degree of attenuation had taken place, which might no doubt, after some time, have gone on to rupture.—*Ibid.*

6. *Perforating Ulcer of the Stomach.*—Of the patients labouring under this disease, noticed by Jaksch, thirty-three had acute tubercle of the lungs, twenty-six chronic tubercle of the lungs, and forty-three pneumonia. He therefore presumes that some relation exists between the affection in question and diseases of the lung. The same physician gives the following sketch of the symptoms commonly observed with this kind of ulceration. After intense mental or bodily exertion, or the use of some stimulating liquor or article of food, the patient complains of violent pain, extending upwards from the pit of the stomach, which often disappears after vomiting. The tongue still remains clean, the appetite is variously altered, and the bowels are for the most part obstinately costive. Sometimes the symptoms assume more of the character of those which accompany mucous gastritis. There is a dull persistent pain in the epigastrium, pyrosis, indigestion, vomiting, and tumefaction of the abdomen. Jaksch, in speaking of the treatment of these cases, recommends the use of milk, veal soup, and chicken soup, as articles of diet. He also recommends, as palliative remedies, leeching and counter-irritation of the epigastric region, anodynes, the acetate of lead, and iron.—*Ibid.*

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE, PARIS.

The most interesting memoirs presented to this Academy during the past month are the following:—

ORGAN OF SPEECH.

M. Bouillaud read a paper entitled "New Researches, destined to shew that the faculty of Articulate Speech resides in the Anterior Lobes of the Cerebrum," in which he considers that he has established,—1st, that severe lesions of the anterior lobes of the brain constantly produce an alteration in the speech, varying from slight disturbance to complete loss of the faculty; 2nd, that disease of the middle and posterior lobes, without implication of the anterior portions, do not affect the speech. From these propositions, M. Bouillaud deduces two corollaries; one respecting diagnosis,—viz., that whenever the speech is more or less affected from disease of the brain, it may be affirmed that the lesion exists in the anterior lobes; another respecting treatment, that if it be necessary to apply remedies as near as possible to the seat of the disease, as the trepan, for example, the forehead is the site to be chosen. The views of M. Bouillaud were warmly contested by MM. Rochoux, Baillarger, &c.

M. Chevallier presented a memoir on the "Presence of Arsenic in certain Mineral Waters."

M. Monneret, one of the Commission sent to the East to watch the progress of cholera, reported his experience of the disease in Constantinople. Nothing of importance was elicited.

M. Dubourg presented a memoir on "Symptomatic Abscess of the Inguinal Region," with the principal object of recommending free opening in preference to repeated punctures.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DES SCIENCES, PARIS.

M. Poggiale lectured on the properties of *aldehyde*, a new anæsthetic agent. He stated that it produced insensibility more rapidly than either æther or chloroform, and in animals had been exhibited without producing any accident.

M. Gaudichaud exhibited a new alimentary plant, received from America, which he called *picquotiane*. It contains a large amount of farina, and is the principal food of some of the aboriginal tribes of central America.

TREATMENT OF HYDROPHOBIA IN THE LAST CENTURY.

METHOD OF TREATING THOSE THAT HAVE BEEN UNDER MY CARE FOR THE BITE OF A MAD DOG, OR OTHER MAD ANIMAL.

If the person's constitution will bear the loss of blood, I take from him 8, 10, or 12 ounces, as soon as possible, and immediately after give him a draught with manna and salts, dissolv'd in an infusion of senna, enough to give five or six stools, and repeat it once a week for the first month. The next morning I prepare for him the following powders:—Loaf Sugar three drams, Salt Petre two drams, Sal Ammoniac one dram and half, made into fine powder, and mixed together, two scruples of which (or as much as you can hold on a shilling,) may be given to a grown person, twice or three times a day, in some warm tea, for the first month, and once or twice a day for the second month. When application hath been made within a fortnight, I have not once had occasion to use any other medicine, though some of them have been terribly wounded; but when it hath been longer omitted, and the dreadfull symptoms appear, such as violent pain and giddiness of the head, fearfullness and trembling at the least noise, a pain of the throat without swelling, which pain extends itself to the stomach, with great thirst, but can not prevail on them to drink,—an hydrophobia, or fear of water, &c. &c. I then treat them as follows:—

August 12th, 1739. A young woman, of as robust a constitution as I ever met with, about 26 years old, was bit by a dog, which after a few days' confinement died mad. Her master and [a] maid-servant were bit at the same time by the same dog: both of them applied to me the fourth day from their being bit. I did for them as above, and they felt no ill effects, but the other laugh'd at them for applying for such a trifle as she called it, and continued well untill the seventh day of September following. As she was in the orchard gathering of apples, she complained of such violent pain and giddiness in her head, that she was obliged to

quit her work and go home to bed. A few hours after, as the family was at supper, she came down stairs with nothing on but her shift, quite void of sense, running at, and endeavouring to bite, every one she came near. The family left the room as soon as possible, but fearing she might hurt herself, two of the men returned, having put on thick gloves, and carrying before them a large hemp sheet, such as is generally used in winnowing: they threw it over her, and getting her down on the floor, bound her as they thought fit. All that night she had no interval of reason, but endeavoured to bite every thing near her, and made a very uncommon noise. The next morning they put on some of her cloaths, placed her astride on a pack saddle, bound her firmly to it, and brought her to my house, which was near five miles from the place she lived at; but on the road, when ever she came near any water, she would be exceedingly fearfull; and after she was at my house, on bringing a bason of water near her, she wd use her utmost endeavours to move from it, and by continuing it in her sight, she wd through herself into great agonies. I kept her in the house some hours, hopeing she might have some interval of reason, but none appearing, having good assistance, I with great difficulty took from her arm twenty ounces of blood, greatly inflamed, having previously put on over her head a woman's thick petticoat, tied close on the top of her head, and likewise round her neck, to prevent her biting, or casting saliva or spittle over us that might hurt us. When after bleeding I had secured her arm, I turned the pocket hole of the coat before her face, and laying her back, I so opened her mouth with an iron spatula that an assistant could drench her with some manna and salts, dissolved in as small a quantity of water as possible; but alas! as soon as it was in her stomach, she was so dreadfully convulsed, that had she not been tied it had been impossible to hold her for several minutes, which as soon as over she was again put on horseback as before, and carried to her father's, which was about a mile and half from. I sent by her friends a quantity of the above powders, to be given her every three or four hours, by force if they could not give it otherwise.

By the time she came to her father's house the physick had purged her briskly, and by six the next morning they had drenched her with five doses of the powder, and some time in the afternoon she seemed a little sensible, though she had not slept from the time she was seized. She now complained of her head, throat, and stomach; the hydraphobia still continued, and she would by no means be perswaded to take her medicines, or any kind of liquid, though she complained greatly of thirst, but were obliged to drench her as before, which wd hurry her prodigiously for some time after. She now lay more quiet, and did not attempt to bite so much as before, and her speech began to be more articulate. The night following she had no sleep, but by the next morning could bear the sight of water, and to have it held near her mouth, but could not prevail on her to taste it, for fear it would bring on the pain of her stomach. The afternoon following she was very sensible, her pains almost gone, her thirst abated, and consented to take her powders dry, and let them dissolve in her mouth, which she cd swallow without much pain, and sometimes wd eat a piece of dry cake. The next night she slept several hours, but not without hurrys, and the next morning she took her powders in some tea, encreasing the quantity of liquid every dose, and frequently took some water gruel, &c., and in a few days was so well as to walk in the fields.

September ye 30th. Thinking all danger over, she went to a child feast in the neighbourhood, where eating heartily, and drinking too much strong beer, she was again seized the next day with all the former symptoms, as violent as ever. On being sent for she was blooded plentifully, and ten grains of turbith mineral given, mixed with a little conserve of roses, and as soon as its operation by vomiting was over, gave her the powders every four hours. The next day, October ye 2nd, towards evening, gave her a second dose of turbith mineral, and ordered the powders to be continued. The next morning all symptoms being better, I gave her only the powders, untill ye 4th of October at night, when she took the third dose of turbith mineral, and thought she seemed quite recovered. She took the fourth dose of turbith ye ninth day, without any laxative after, yet her mouth was not sore with it. I advised her to take the powders twice a day for six weeks, and afterwards once a day for a month or six weeks longer, which she accordingly did, and being afterwards very carefull of what she eat or drank, she had no return, but hath enjoied a very good state of health, being since married, and hath a large family of children.

During each time she had the hydraphobia her pulse varied greatly, sometimes so strong that I shod have taken off more blood, had they not in a few minutes been so small and intermiting that I was fearfull she was dying, when on a sudden they wd rise again, and beat as regular for some time as in a well person, and so wd be altering several times in one hour; neither was she ever free from a subsultus tendonum during the hydraphobia.

Since the above case I have met with three other persons who had the hydraphobia, &c., as above, before I was applied to. Immediately after bleeding I gave a dose of turbith mineral every, or every other day, unto the third or fourth time, according as the symptoms encreased or decreased, continuing the powders as in the above case. I have always charged those that were bit not to use any spirituous liquors, wine, strong beer, high seasoned meats, nor spices. I dressed the wounds as if bit by a dog that was not mad, only that if it was in a place where I could conveniently keep it open as an issue, I did so for sevl months. The first opportunity I had of giving the above powders, was in the month of June, 1724, since which time I have had under mine, and my apprentice's care, upwards of three hundred persons for the bite of mad dogs, cats, &c., all which, by the blessing of God, on the above medicine, have been happily preserved, without failing in one case.

JOHN DYER.

Crediton, September 11th, 1759.

Purging Salts one ounce, Manna half an ounce, dissolved in a tea cup of Senna Tea.

General Retrospect.

PATHOLOGY.

CO-EXISTENCE OF SMALL-POX AND SCARLATINA.

Later experience has had frequent opportunties of subverting the Hunterian maxim, that "two fevers cannot co-exist in the same constitution," &c., but it seldom happens that it is shown more strikingly than in the cases in point related by Mr. Marson, in which variola and scarlatina existed at the same time in the same patient. There is reason to suppose that the occurrence is not so infrequent as might be supposed, as the author has himself seen seven instances, and others are in various British and Foreign Journals, the references to which are given in the original. It is probable that this exanthema is often mistaken for the erythematic or erisipelatous flush, which accompanies the confluent form of the disease. In this case the state of the throat and larynx rendered a mistake impossible. —*Medico-Chirurgical Transactions*, 35.

APHTHÆ, OR THRUSH.

On the semeiological value and the prognosis of thrush, a material difference exists between the opinions entertained by Dr. Valleix and Professor Trousseau, both of whom are attached to a hospital devoted to diseases of children. M. Valleix considers thrush as the symptomatic expression of some serious internal complaint; M. Trousseau, on the contrary, looks upon it as a local disease, often resulting from general debility, but not by any means so fatal in its import as M. Valleix conceives it to be. The false membranes, in which recent microscopic investigations have shewn the existence of parasitic vegetations, have no tendency to invade the larynx or nasal fossæ, but they readily spread to the œsophagus, and even to the stomach and intestines. Idiopathic thrush may be developed with a considerable degree of violence, the child preserving all the appearances of health. Suction only is imperfectly performed, being a painful operation to the diseased mouth. It is unattended by vomiting, fever, or dyspnœa, and yields easily to local treatment. M. Valleix, on the other hand, endeavours to establish that aphthæ confluentes are the result of a general disease, preceded by vomiting and diarrhœa, accompanied by erythema and desquamation of the skin, and generally terminating in fatal pneumonia. In answer, M. Trousseau states that, when debilitated infants are placed in unfavourable hygienic conditions, they are very prone to contract diseases, which, if they last, are soon complicated by aphthæ. Absence of proper food, care, and cleanliness, impoverish the blood, and, besides, expose the skin to the continued contact of irritating matter; hence excoriations and even ulcers. If properly treated all the patients recover. The treatment consists in applications of borax and honey, frequently repeated.—*Journal des Connaissances Méd. Chir.—Medical Times.*

DISSECTING ANEURISM.

Dr. Pirrie reports the following case:—A man, aged 50, who had died suddenly, was examined. In the arch of the aorta, almost three-quarters of an inch to the left of the origin of the left subclavian artery, there was a rent of the inner and middle coats. From this rent to near the origin of the aorta, on the cardiac side, and for upwards of an inch on the capillary side, the external coat was separated from the middle, around two-thirds of the circumference of the artery. From the aneurism thus formed there was an opening of upwards of half an inch in diameter, through which it burst into the pulmonary artery. The aorta was steatomatous in many parts, as was likewise the pulmonary artery.—*Monthly Journal*, Nov., 1847.

RUPTURE OF THE CHORDÆ TENDINEÆ ON THE RIGHT SIDE.

Dr. Bentley Todd narrates an instance of this rare accident, followed by pathological remarks of considerable interest. The case is that of a man, aged 21, who received a knife wound in the right side, in a scuffle, which was followed by pleuritis, necessitating large and repeated venesection. A month after the injury he vomited blood, and subsequently had repeated sanguineous discharges, both from stomach and bowels. When admitted under Dr. Todd's care, he was anæmic, with general anasarca, indurated and enlarged liver, hacking cough, and orthopnœa. After death, the immediate cause of which was rapid effusion of serum into both pleuræ, the heart was found to be hypertrophied and dilated, especially on the right side. The valves were healthy, with the exception of the tricuspid, the anterior or larger portion of which floated loose in the ventricles, being detached from the corresponding carneæ columnæ by rupture of the tendinous cords. The musculi papillares were sunken and atrophied, evidencing the old date of the rupture.

In his comments on the case, Dr. Todd remarks, that the accident appears to have been the result of undue tension of the cords. This can only arise from anormal distension of the ventricle, such as might arise from obstruction to its outlet.. Such an obstacle in the present case is conceived to have been offered, by the impediment to the pulmonary circulation, induced by the respiratory disturbance during the struggle before mentioned.

The symptoms were progressive and evidently due to the regurgitation allowed by the ruptured valve. Dr. Todd alludes to the fact, that a certain amount of regurgitation is a normal condition, as pointed out by Mr. Wilkinson King, but in the present case this normal reflux was much exceeded. The sequence of effects would be distension of the vena cava, of the hepatic and intestinal veins, and lastly, of the general venous system. As secondary effects to the venous congestion, would be arterial engorgement, and consequent dilatation and hypertrophy of the left ventricle, and hence again pulmonary engorgement. The symptoms of the case are readily explained by their pathological effects. Dr. Todd calls attention to the hæmatemesis, which he considers (justly, no doubt,) to have been induced by the distension of the hepatic venous system, and states it as his belief that the symptoms may be discovered as a frequent accompaniment of anormal tricuspid regurgitation.—*Dublin Quarterly Journal*, February.

ALKALINE URINE.

Dr. Rees points out that urine secreted normally acid, may become alkaline during its passage through the urinary passages, independently of delay in the bladder, and that such cases are benefitted by alkaline medicines. He narrates a case in illustration, of a woman who passed alkaline offensive urine, in conjunction with small lithic calculi. She got worse under acids and was cured by Liquor Potassæ in Decoctum Pareiræ.—*Medical Gazette*, April 7th.

CHLOROFORM IN INFANTILE CONVULSIONS.

The following instance is recorded in the Boston *Medical and Surgical Journal*, by Mr. Sabine :—

I was called to see a child, five months of age, who for nearly two hours had been labouring under the most severe and unremitting convulsions that it has ever fell to my lot to witness in an infant. There was a constant spasmodic jerking of the muscles of the arm, together with the diaphragm and abdominal muscles. Respiration was so much impeded, and had been for so long a time, that there was strabismus of both eyes, owing, probably, to the presence of partially arterialized blood in the brain. The surface was growing more and more cold and livid, and a clammy sweat stood out upon the little sufferer's face and temples. As various antispasmodics had been tried without relief to the patient, I decided upon using chloroform. But a few inhalations were made before the eyes rolled up, the spasm of the muscles ceased, the breathing was free and easy; in fact the child "came out of the fit." The pulse, which had been absent from the wrist before the administration of chloroform, was perceptible at once, and the surface of the body grew warm. In about three minutes entire consciousness returned, and in a short time the babe nursed.

Means were then adopted for regulating the disordered state of the bowels, upon which the convulsions were probably dependent. No vomiting, and no unpleasant effects whatever, followed the use of the chloroform in this case. The nervous system was fortified against it, just as in acute tetanus, patients will bear enormous doses of brandy or opium.

MEDICAL JURISPRUDENCE AND TOXICOLOGY.

FATAL WOUND OF THE UTERUS, WITH TEARING AWAY OF THE INTESTINES, NOT FOLLOWED BY IMMEDIATE DEATH.

M. Tardieu (*Annales d' Hygiéne*,) reports a horrible case which recently came before the French tribunals. The violence in question was committed by a peasant on the person of his wife, seven months pregnant. The woman was heard supplicating for mercy *three quarters of an hour* after portions of her intestines had been seen in the yard, thrown there by him. On examining the body no traces of external violence were observed. A large quantity of blood was found in the cavity of the abdomen, with extensive lacerations of the vagina, uterus, and peritoneum, the edges of which shewed that a cutting instrument had not been employed. The whole intestinal canal from near the pylorus to the ileo-colic valve, was completely torn away.

Cases analogous to this are on record. Suicides have given issue to the abdominal viscera without causing immediate death. In respect of the uterus itself Dezeimeris cites fifteen cases in which the women have survived several hours and even weeks. Other writers gave cases in which the intestines protruded through the rent in the uterus and have sphacelated. The author relates a case in which the uterus and intestines were torn away by a pupil, and in which the patient lived several minutes; and Mauriceau has a similar case, the woman surviving an hour.—*British and Foreign Med. Chir. Review*, April.

[A notice of a case which occurred in the neighbourhood of Chesterfield, where the uterus was mistaken for the after-birth, and torn away, will be found in the *Provincial Journal* for 1845, p. 115, and at p. 168 of the same volume is an account of the inquest on a similar case which occurred at Costessey, near Norwich, In this latter instance a portion of the large intestines, as well as the uterus was forcibly removed. Death took place in the first case a few minutes after the infliction of the injury; in the other the patient survived half an hour.]

PARALYSIS PRODUCED BY ARSENIC.

Dr. Clark related to the New York Medical and Surgical Society, the case of a young woman who, five months ago, took arsenic for the purpose of self-destruction. According to her own account she purchased sixpence-worth, amounting to three tablespoonfuls, all of which she took. This was about 11 p.m. Warm water was given her, and vomiting produced. At 3 a.m., she was taken to the New York Hospital, where the stomach-pump was used, the hydrated sesquioxide of iron having probably been previously administered. She had afterwards some fever, but gradually became better. Eight days after taking the arsenic she was seized with severe pains in the upper and lower extremities. The parts were swollen, but neither red nor hot. Three days after this she lost almost entirely power over her extremities; she has since continued bed-ridden, and is now at Bellevue. She can move her arms freely, and can close and open her hands, but with no force. The feet are still paralysed, but she can bend the knees.—*New York Annalist.*

SUICIDE OF DR. HORACE WELLS, OF HARTFORD, CONNECTICUT, U.S.

Dr. Wells, the discoverer of the anæsthetic properties of æther, having been placed in confinement on a charge of vitriol-throwing, committed suicide by cutting the femoral artery of the left thigh with a razor. Previously to the fatal act, he inhaled some chloroform to produce insensibility to pain. When discovered he was quite dead, and the cell in which he was confined was a pool of blood. On the floor were scattered several sheets of paper, on which the unfortunate man had written a history of the vitriol-throwing, the use and effects of

chloroform, and the causes that led to his depriving himself of life. In one letter, he says he became acquainted with a young man who frequented his office, as a dentist, that his friend called and said he would thank him (Dr. Wells,) for some vitriolic acid, with which to pay back a loose female, who injured his (the friend's,) dress—that he complied with the request of the young man, and that they prepared a phial to squirt the acid, by making a groove in the cork-stopper thereof. The letter goes on to say, that they then sallied out into Broadway—that they met the female, on whose person vengeance was to be doled out—and that his acquaintance did so avenge the former injury.

The friend then proposed that they should "*continue the sport,*" to which he gave a direct negative. They then parted, Dr. Wells going home. Afterwards he explains how he was accustomed to the use of chloroform, which he inhaled over and over again to produce sensations of exhilaration. Two evenings after the one above mentioned, he used the chloroform, and in a moment of delirium he seized the phial of vitriol which was on the mantel, and rushing out into the street, commenced throwing it on the persons of the females who walked Broadway.

The following is the conclusion of his statement in his own words:—"I lost all consciousness before I removed the inhaler from my mouth. How long it remained there I do not know, but on coming out of the stupor I was exhilarated beyond measure, exceeding any thing I had ever before experienced, and seeing the phial of acid, I seized it and rushed into the street and threw it at two females, I may have thrust it at others, but I have no recollection farther than this. The excitement did not leave me for some time after my arrest." He says he did not so much care to free himself from blame by this communication, as to give to the world the real facts in connection with the fatal circumstances. The reason he gives for the crime on his own person which he was about to commit is, that he abominated the idea of doing mischief, and that he felt that his character was irrecoverably gone. In speaking of his wife and child, he says most feelingly, "Oh my God protect them. I cannot proceed, my hand is too unsteady, and my whole frame is convulsed in agony: my brain is on fire."

"Sunday, 7 o'clock, p.m.

"I again take up my pen to finish what I have to say. Great God has it come to this? Is it not all a dream? Before 12 to-night to pay the debt of Nature; yes, if I were to go free to-morrow I could not live and be called a villain. God knows I am not one. Oh my dear mother, brother, and sister, what can I say to you? My anguish will only allow me to bid you farewell. I die this night believing that God, who knoweth all hearts, will forgive the dreadful act. I shall spend my remaining time in prayer. Oh what misery I shall bring on all my near relatives, and what still more distresses me is the fact that my name is familiar to the whole scientific world as being connected with an important discovery. And now, while I am scarcely able to hold my pen, I must to all say farewell! My God forgive me! Oh my dear wife and child, whom I leave destitute of the means of support, I would still live and work for you, but I cannot; Did I live I should become a maniac. The instrument of my destruction was obtained when the officer who had me in charge permitted me to go to my room yesterday. "Horace Wells."

"*To the Editors.*—My last request to Editors is that they will, while commenting on this unhappy affair, think of my poor wife and child, also my mother, brother and sister, all of whom are amongst the most respectable members of society.

"*To my dear Wife.*—I feel that I am fast becoming a deranged man, or I would desist from this act. I can't live and keep my reason, and on this account God will forgive the deed. I can say no more.

"*To Mr. Dwyer, Western Hotel, Courtlandt Street.*—Dear Sir,—When you receive this I shall be no more. I wish you would take my watch and present it to my dear wife, together with the trifle I have already given you. Please to attend to my burial, and let me be interred here in the most secret manner possible. I wish you and Mr. Barber would go immediately and reveal this misfortune to my wife in the most unobjectionable manner possible, and attend to the business which we spoke of this morning, when you little thought of this occurrence.

"Horace Wells.

"Messrs. Dwyer and Barber, Western Hotel."

The deceased, as it is supposed, previously to committing the rash act, saturated a new silk handkerchief with the chloroform, and placed it to his mouth, where it was found tied by another silk handkerchief round his head. He was about 35 years of age.

[The foregoing particulars relative to this extraordinary case are extracted from an American paper. We give the letters entire, as exhibiting the state of mind of the writer at the time or immediately before the committal of the fatal act.]

NOTICE OF THE LATE MR. P. N. SCOTT, OF NORWICH.

Page Nichol Scott, Esq., of Norwich, died, April 27th, in the 67th year of his age. He was the oldest practising surgeon in that, his native city, and before fixing himself there, was engaged at the Naval Hospital at Haslar. To this period of his life he always referred with emotion, on account of the opportunities it afforded him, not only of professional instruction, but of shewing acts of great kindness and attention to the sick and wounded French prisoners who came under his care.

Mr. Scott settled in Norwich in 1809, introduced as the partner of Dr. Rigby, on whose retirement he was chosen Assistant-Surgeon to the Norfolk and Norwich Hospital, thus filling the vacancy created by the late Mr. Dalrympie's promotion to the Surgeoncy; but not finding himself at ease in the prospect of the public duties to which this appointment was sure to introduce him, Mr. Scott resigned in 1819, after having officiated as Assistant-Surgeon for five years.

Mr. Scott turned his attention particularly to midwifery, in which department he conducted a most extensive practice; and few men have received in the provinces greater support than himself, or more promptly attended

to the sudden calls for his assistance by all classes, from the lowest to the very highest in society. His constant study was to do grateful and kind acts to his patients, as well as to his friends, and he saved himself much discomfiture in untoward and difficult cases, to which he, without hesitation, called the aid of his contemporaries of the profession, with whom he lived on terms of friendly and generous intercourse.

For thirty-three years Mr. Scott was surgeon to the Norfolk County Gaol, which afforded equal scope for the exercise of his philanthropy and his professional skill. On recently relinquishing this onerous appointment, he received the thanks of the magistracy, which were re-echoed by the public local press; but he was not deemed entitled to a retiring pension, the appointment being annual. Although in easy circumstances, questioning the correctness of this opinion of the magistrates, Mr. Scott thought it due to his professional brethren, whose official appointments might render them interested in the matter, to obtain the highest legal opinions, which were to the effect, that "the surgeon to a county gaol is entitled to a retiring pension by Act of Parliament, equally with other officials." It was a source of great rejoicing to the subject of this brief notice, that he obtained this favourable view to the question, although he was not destined to experience the fruits of its final decision.

There is one trait of character, and one act, which deserves to be revived on this occasion, not less for public purposes, than for the eulogy of an individual. Mr. Scott took a conspicuous part with Messrs. Crosse, Johnson, and others of his friends, in procuring the commutation of the sentence of a poor pregnant woman, whom the verdict of an ignorant *jury of matrons* had pronounced not *quick with child*. The publicity given to this case, chiefly through Mr. Scott's efforts and zeal, has told favourably in like instances since, by rectifying other similar errors, and will ere long, it is to be hoped, remove from our statutes the necessity for an appeal to the ignorant and uneducated on similar painful occasions.

The decease of Mr. Scott was preceded by several months of severe suffering and privation, from an encephaloid tumour of the abdomen, and during this trial he still turned his mind to many acts of kindness, and closed this scene of sorrow, not without many touching appeals to those about him, whether he had not endeavoured to be "father to the fatherless, and a reliever of the widow's distress."

THE ACTIONS AGAINST THE MIDLAND RAILWAY COMPANY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

If the Midland Counties' Surgeon, who has volunteered his services in defence of the Midland Railway Company, and made such an unwarrantable attack upon the conduct of the Coleshill' surgeons, in the case of Higgins, the poor man who met with the accident on their line of railway, at Whitacre, on the 9th day of February, 1848, will furnish me *publicly* with his name and address, I will endeavour to correct the errors which he has fallen into; but I am not disposed to answer the attack of an anonymous correspondent.

I am, Sir,

Your obedient servant,

J. DAVIES, M.D.

Coleshill, May 19, 1848.

THE "PRACTICAL" MAN.

There are medical men, who, from a want of study, of intelligence, or from natural indolence, or from being too old to master recent improvements, affect a supreme disdain for everything which concerns doctrine. They call themselves PRACTICAL MEN and speak ironically of *theorists*,—such as labour for the advancement of medical science, and whose knowledge crushes and confounds them. These "practical" men have no doctrine, no general principles; they gather together ready-made formulæ and isolated cases, without any kind of scientific discernment. We have frequently had to remark, that a practical man,—that is a man who boasts of knowing nothing of scientific medicine, is intellectually inferior to a master mason or cabinet maker, for these have principles which they apply in their business.—*Monthly Journal*, April.

Medical Intelligence.

THE EPIDEMIC CHOLERA.

We regret to state that the epidemic cholera has again broken out at Constantinople, and on the Eastern frontiers of Russia, and at Moscow.

APPOINTMENTS.

Her Majesty the Queen has been pleased to confer the honour of Knighthood upon John Liddell, M.D., F.R.S., Medical Inspector of Fleets and Hospitals, Royal Hospital, Greenwich.

M. Michon has been appointed Surgeon to the Hospital La Pitié, Paris in the room of M. Laugier.

M. Maisonneuve has been appointed Surgeon to the Hôpital Cochin, in the room of M. Michon.

Dr. Cotta, Surgeon to the Hospital of Lodi, has been appointed Professor of Clinical Surgery, in the University of Padua.

Dr. Geromini has been appointed Professor of Clinical Medicine, in the University of Parma, in the room of Dr. Tommasini, deceased.

ROYAL SOCIETY.

Amongst the candidates for the Fellowship, selected by the Council as eligible for the honour, are William Fergusson, Esq., of King's College; Dr. Robert Gordon Latham, of the Middlesex Hospital; Dr. James Ormiston M'William; James Syme, Esq., late of University College; and Dr. Allen Thomson, of Edinburgh. The Earl of Rosse is to be put in nomination for the Presidency, in the room of the Marquis of Northampton.

UNIVERSITY COLLEGE, LONDON.

The resignation of Mr. Cooper as Professor of Surgery at this Institution, has been followed by that of Mr. Syme, the newly-appointed Surgeon to the Hospital, and Professor of Clinical Surgery.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, May 12, 1848:—J. S. Rimington; J. Delves; R. Wailes; J. Manley; W. D. Jagoe; E. Carver; S. G. Chuckerbutty; R. Hagyard; H. Spicer; J. J. Williams; J. Hinton.

Gentlemen admitted Members on Friday, May 19, 1848:—F. T. W. Ford; J. N. Coffin; C. Carey; M. Simpson; J. S. Shackles; P. H. Bird; H. C. Shepard; T. E. Ladd; J. R. Morgan; H. Stuckey; R. Harold; J. Kay.

Gentlemen admitted Members on Friday, May 26, 1848:—E. Whittaker; R. Hilton; T. B. Holland; J. Wyatt; A. P. Rayner; J. Harrey; G. Taunton; J. L. Parke; R. Hicks; H. M'Cann.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates Monday, May 11th:—Richard William Broster, Poole; Charles Alexander Bissett; Charles James Bennetts, Mylor, Cornwall; Robert Oke Clark, Farnham; Francis Phillp Francis, Colchester; William Maltby, Southwell; Dannett Asbury, Enfield; Maurice Levett Manthorp, Thorp, Colchester; Martin Wales Bedell Coulcher, Downham; George Wallis Berkeley Calcott, Clifton, Bristol; Arthur Goodchild, St. John's Wood; Robert Hagyard, Hovingham.

Thursday, May 18th:—John Penberthy Berryman, Penzance; Henry Rowland Hoskins, London; Geo. Dunn, South Molton; Charles Drage, Ipswich; Scholes Butler Bird, Leamington Priors; Frederick William Pearce Jago, Bodmin; James Edward Neild, Oulton, near Leeds; Thomas Goodall Copestake, Kirk Langley, Derbyshire; William Perry, Stonehouse, Devon; Jas. Murray, Oldham.

OBITUARY.

Died, May 5th, at Birkenhead, Alexander Hannay, M.D.

May 6th, at Montrose, John Duke, Esq., Surgeon, R.N.

May 7th, at Willowbank, Airdrie, aged 56, Walter Rankin, M.D.

May 21st, at Killeshandra, aged 43, James Alexander Finlay, Esq., A.B., F.R.C.S.I., Medical Attendant of the Killeshandra Dispensary.

May 24th, aged 71, M. Guersant, (père,) physician to the Hôpital des Enfans, Member of the Académie de Médecine, &c.

Recently, aged 73, Dr. D. Salvador Massy Ribé, of the University of Huesca, author of several treatises on yellow fever and on intermittent fever.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNIVERSARY MEETING.

From some unforeseen circumstances, and in particular the severe illness of the President elect, the Taunton Branch of the Provincial Medical and Surgical Association are prevented receiving the members at the Anniversary Meeting appointed to be held at Taunton in August next. In compliance with an application from the Council, and from a deputation from Taunton, the members of the Bath Branch have kindly consented that the Anniversary shall be held in that city. The arrangements for the meeting are rapidly progressing, and will be published in the next number of the Journal.

NOTICE TO MEMBERS.

Gentlemen who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due, either to the Secretary of the District in which they reside, or to the Treasurer or Secretary of the Association.

ROBERT J. N. STREETEN, Secretary.

YORKSHIRE BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNUAL MEETING.

The annual meeting of the above Branch will be held on Thursday, June 8th, at twelve o'clock, in the Hall of the Philosophical and Literary Society, Leeds. W. Hey, Esq., President-Elect, will occupy the chair.

N.B.—Visitors admitted on the introduction of a member.

W. D. HUSBAND, Secretary.

SUFFOLK BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNUAL MEETING.

The Annual Meeting of the above Branch will be holden at the Guildhall, Bury St. Edmunds, on Friday, the 16th of June, under the Presidency of Dr. Hake.

C. R. BREE, Hon. Sec.

Stowmarket, May 27, 1848.

TO CORRESPONDENTS.

Communications have been received from Mr. Crosse; the Birmingham Pathological Society; Mr. Paget; Dr. Wardell; Dr. Oke; Mr. Crompton; B. D.; Mr. C. Anderton; Mr. T. Hunt; Mr. G. Moore; Mr. S. J. Salter; Dr. Simpson.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

REMARKS ON THE PRESENT ASPECT OF MEDICINE.*

By W. Newnham, Esq., Farnham.

But the crying evil of the present day is the widely spread contagion of empiricism existing in its various forms, in forms which are too frequently overlooked, but which, though they cannot be reached by legislative enactment, are as fully worthy of attention, and as fearful in their consequences, as if their origin were proclaimed by the broad Government stamp upon their surface.

The *past* age of medical investigation was particularly characterized by its almost exclusive fondness for narratives of single cases of disease, to the neglect of opinions, and in entire forgetfulness of the axiom, that individual histories are of no value, except in so far as they admit of being classified and arranged, and of thus forming a basis for the legitimate deductions of cool and sober reasoning. This unfortunate bias, however, was the creature of feeling, and arose mainly from the self-gratulation dependent upon an escape from the imaginative diagrams of the mathematical, the reveries of the mechanical, or the wilder musings of the chemical physicians of the olden time, and seemed like a transition from the dreamy region of conjecture, to the positive realities of *fact*. Hence arose a laudable determination to avoid for the future, the rocks and shoals of similar hypotheses—a determination aided not a little by the natural indolence and love of ease, which are so congenial to the human mind, and which have been so much fostered by the superficial and sketchy education of bye-gone years. There is, however, no royal road to excellence; and even among the monomaniacal accumulators of *facts*, there were not wanting those who perceived, that if ever the science of medicine should acquire a greater degree of certainty than it enjoyed at that moment, it could only be obtained by diligent observation, aided by dispassionate reasoning. Facts are of no value, except as the ground-work of opinions; and again, opinions are useless, unless they can be referred to *principles*, upon which the goodly structure of every-day thought, and reasoning, and conduct, may be successfully reared.

This is especially true with regard to *medical facts*; for in addition to many other sources of fallacy, in recording the history of disease, there exists this peculiarity,—viz., that no two individuals will similarly observe the same appearances, or will derive from them impressions which are identical. This source of error is not indeed limited to medicine, but is also traceable in all except the exact sciences; and it will remain insurmountable, so long as the manifestations of mind are characterized by an infinite variety of physical constitution, and so long as the notices of external objects, conveyed through an infinite series of cerebral organizations, shall produce corresponding, and therefore infinitely varied, impressions, upon the thinking, reasoning, judging principle.

There, are, however, general rules in medicine; the first principles of the human constitution are uniform, and that alone will be good practice which consists in applying and modifying these rules, according to the greater or less prevalence of those active principles in each individual case. Here again there are two sources of error; the first, of adhering too exclusively to opinions invested with their imposing but surreptitious garb of general principles; and, secondly, of being induced to modify and change those general principles upon the result of a small number of disjointed cases. The influence of the former constitutes the hypothetical, that of the latter the empirical, practitioner.

We must admit, as a general rule, that in most, if not in all, the numerous effects of mental empiricism, there must be some good, in order to give currency to the associated evil. Unmixed evil is never long tolerated, and therefore some good, real or fancied, must arise from certain plans which have obtained reputation; and in these cases the evil arises not so much from the nature of the remedy, as from its indiscriminate employment for varying, dissimilar, and even opposite conditions. Such is oftentimes the effect of mental impression, as to induce or to supersede disorder. Everybody knows the familiar exposition of both these truths; the former, in the production of hysteria, and many dyspeptic conditions; the latter, in the influence of charms upon ague, in certain constitutions.

Perhaps the characters of empiricism were never more strongly marked than in their earliest incarnation. Paracelsus, an individual without deep learning, disdaining literature, without refinement of mind, skilled in alchemy, astrology, and all the mysticism of that still mystery-loving and quack-creating country, neological Germany, assuming that disease and its remedies are to be found in the Bible, and that

* Continued from page 285.

an indefinite prolongation of life was attainable by obedience to the will of Heaven, and by relying upon the influence of the planets, rather than by observing symptoms, considering disordered functions, and administering appropriate remedies; and finally, affirming the cure of surgical disease, without the aid of surgical remedies, merely by magical words and cabalistic processes. In this history we trace the earliest sample of the mental empiric, and the "*Opera omnia*" of Paracelsus, and the "Fallacies of the Faculty" of modern date will one day be consigned to the same unhonoured tomb, with this difference probably, that the one flourished in the dark ages of mysticism, and proved the fallacy of his own infatuation, by an early death; whilst the latter has not the excuse of living in the dark ages, nor the opportunity of concealing, in the nineteenth century, under the ample folds of assumed universal benevolence, the too glaring purpose of "*quocumque modo rem.*"

It is much to be regretted that the monograph upon which we have been recently commenting, should have occasioned the following tempting addition to an advertisement of the chrono-thermal system:—"Fallacies of the Faculty, 'Young Physic.' Under the sportive appellation of Young Physic, the *British and Foreign Medical Review* has at last done justice to the chrono-thermal system. Young Physic is chrono-thermalism in disguise. The great success of this system has reluctantly wrung from Dr. Forbes the humiliating confession that he has been all his life practising in error: 'our system,' he says, 'is radically wrong.'"

The beneficial influence of the Royal touch in the king's evil, *if at all true*, and if not dependent upon magnetic conditions, must have been based upon that kind of mental agency, through which such an invigorating impulse was given to the constitution as enabled it to take the place of steel and other tonic remedies. But as the practice has fallen into desuetude, it is to be inferred that it has also fallen into disrepute, either from the efficacy of the touch having worn itself out by time; or from the diminishing circle of magic ignorance and superstition; or in consequence of having been superseded by some newer and more attractive object of faith.

We pass over a variety of panaceæ which have fretted their little hour upon this life's broad stage, and then passed into complete oblivion, in order to arrive at two glaring monstrosities, each claiming the same natural birth-place, though emanating from a very different parentage; the one, we charitably hope, originating from the overheated brain of perverted genius; the other, claiming its frigid embryo life from the cool calculating brain of an uneducated peasant,—viz., homœopathy and hydropathy. There is nothing new under the sun,—and it may be truly said of these great heresies that each contains some acknowledged truths, not newly discovered, but established of old. Every error, however fatal, must, as we have remarked already, possess some fraction of truth, in order to its obtaining currency. That which is manifestly false is rejected at once by the common sense of mankind; and there must be some truth in order to render error specious, and to save it from universal reprobation. So may it be said of homœopathy and hydropathy, that what is true in each is not new, and that which is new is not true. We admit, and daily act upon many of the principles of the former, and we may even believe in the great efficacy of rationally small, and minutely-divided doses; but when we are gravely taught to expect 897 various symptoms to be produced by the millionth part of a grain of common salt; 938 from a similar dose of carbonate of potass; 1,000 from an equal dose of pure lime; and more than all, both in number and absurdity, 1,090 from a co-ordinate dose of its carbonate or common chalk; we shall not, perhaps, be deemed uncharitable in suspecting the veracity or the sanity of the observer. So, also, we feel the value of cold water; it has long been upheld as the great Catholicon for fever, when taken into the stomach, and cold affusion has had its talented and enthusiastic advocates, and perhaps, even now, may have experienced some degree of more than deserved forgetfulness; and we honestly avow our own admiration of cold water universally applied as a means of health, and cleanliness, and comfort, and our conviction of the criminal neglect of this life-preserving agent, even in cleanly England. We aver that the important recommendations of Hippocrates, and Hoffmann, and Currie, should never be lightly esteemed; but when we are invited to swallow all the absurdities of modern hydropathy, we may well hesitate at that grievous fanaticism which has already consigned so many victims to a premature grave. Admitting therefore the small infusion of truth which attaches to these errors, and the semblance of honesty which gives currency to their nefarious influence, we must mention one other property which they possess in common with all other remedies of a similar class, viz., *the universality of their undiscriminating application.* In all, and precisely opposite states of the system—in the presence, and during the absence of fever—in asthenia and hypersthenia—in anæmia and hyperæmia—in congestive and inflammatory action—in summer and in winter—in every variety of season, and climate, and habit, and constitution—in the incipient stage of disordered function—and in the fast approaching termination of organic disease,—in every age and sex—and under every conceivable variety of circumstance and locality, still the same remedies are applied, and applied indiscriminately.

Before mentioning the principles which regulate the effects of this and other forms of quackery upon the mind, we must stigmatize with severest reprobation, a class of exclusive practitioners, whose conduct admits of no palliation, and whose selfishness is diametrically opposed to the very basis of our self-denying profession. We had thought of mentioning a certain and increasing class of professional exclusives; but we would willingly draw the veil of deepest oblivion over their delinquencies, and we eagerly pass on to notice the effects of empiricism upon the human mind, and some of the more common effects of professional empiricism.

In all the vaunted results of quackery, the good effects are produced, not by the medicine exhibited, but by certain mental influences,—by altered habits of

life,—by implicit credence in the promises held out,—by undeviating obedience to the rules enjoined,—by change of air, exercise, scenery, and association;—in short, by a combination of many circumstances, all possessing for their basis this one principle—a development of mental confidence, and an excitement of mental belief and expectation, amounting (as is generally the case on subjects of which we have no actual knowledge,) to the strongest degree of fanatical credulity.

Admitting, however, this to be the case, we shall at once perceive that the attachment to quackery is founded upon a principle of our nature, very extensive in its agency, and therefore very difficult of eradication, because the principle of undoubting belief is powerful in proportion to our ignorance on the subject matter of our confidence.

A common result of this principle is, that we constantly do that which we believe we can accomplish, though confessedly difficult; and that we constantly fail of effecting that, however easy, about which we are desponding, and simply because we are *so despondying*. We digest that which we eat with relish and confidence; we get indigestion from that which we eat with fear and apprehension. There is no medical man who has not observed the increased benefit arising to his patient from the medical means employed, when that patient pursues those means with unbounded confidence; and who has not experienced the impossibility of getting on with those whose minds have been set afloat by doubt—by the suggestions of friends—by the unguarded vacillation of the doctor—by questioning the utility of present plans, or by apprehension of any kind. Hence it happens to those patients whose confidence has been exhausted in their own rational medical man, that they throw themselves with unbounded practical credulity into the hands of those who will condescend to more of mystery,—who will reason less and promise more. The unblushing pretender who thinks of nothing but his own interest, and with whom the end will sanctify the means, will be sure of success in such a case, over the honest man of science, because he can promise largely and risks nothing by failure. The instances of credulous success are loudly bruited,—the 10,000-to-1 instances of failure are buried in the grave, and hidden from the sight, as if they had never been. And therefore it is, that so long as we have weak and credulous patients, and so long as we have cases of long-standing malady, and irritable nerves, and exhausted patience, so long shall we find it impossible to control the disposition to encourage quackery by the public, through any legislative enactment.

Here let me ask, do not many worthy and excellent medical men avail themselves of this principle beyond its just and legitimate influence? So long as they cultivate the principle by inspiring the confidence of their patients, through diligent cultivation of the means of professional improvement, both practical and literary;—so long as they are known to be men of deep research, and accurate and unprejudiced observation;—so long as they have a character for promptitude and decision in their measures, and skilfulness in the application of their means to the severest emergencies of daily difficulty;—so long as they are acknowledged to be men of good common sense, and always capable of giving a reason for any requirements which they may make;—so long as they maintain a reputation for veracity and honesty, and transparency of purpose;—so long as they are known to be men of upright conduct, and are remarkable for kindness of heart, benevolence of feeling and real active sympathy with the miseries of their fellow creatures;—so long as it is obvious, that though they must live by their profession, yet that their *first object is to do good*, and that they are always ready to join in every attempt to supply every want, *moral* as well as *physical*; and that from having lived much in the world with an intuitive perception which none but a medical man can possess,—and that from having brought their knowledge of man and his perversities, to the study of man and his morbid conditions,—and from having done so, with views enlarged by general knowledge, and softened by kindliness of disposition, they have acquired a certain superior degree of tact in his management;—so long will the influence over the patient be legitimate, whose confidence will be well placed, and whose repose will be securely rivetted on the assurance that his medical friend will not deal in promises beyond what there is a reasonable prospect of fulfilling.

But when the professional man seeks to establish his claims to confidence on less transparent grounds,—when he enwraps himself in mystery, and purposely mystifies for the sake of beclouding his patient,—or when he undervalues the means of art, and proclaims the omnipotence of nature, guided by his regimenal views,—or when he arrogates to himself a knowledge superior to others, and a power to relieve inherent in himself;—when he strangely undervalues the opinions and judgment of his compeers, in order to exalt his own conceptions;—or when he makes up for his ignorance of general, scientific, and professional literature by confident assertion,—when he unworthily condescends to act upon the agitated mind of the invalid, to deliver a fearful prognosis in order to enhance his skill if the patient recover, and to secure for himself a safe retreat, if the issue of the case be unfortunate,—when he seeks to exalt himself by the history of his own cures, and to abuse his patient's mind with fictitious or exaggerated narratives,—when he stoops to give up his own opinion, or rather to possess none, but to take the shape and mould of those with whom he is associated,—when he condescends to convey false notions of present right and wrong, and false views of religion, only to pacify and please on the one hand, or to excite fears and to promote influence on the other,—and finally, when he gives too good, or too unfavourable a view of a case, in order to maintain his own influence, then is that influence illegitimate,—then is he deeply guilty of mental empiricism.

These general views will naturally introduce a very few remarks on the various forms assumed by this deeply-rooted and widely-spreading disease, the first and most frequent of which will be found in the routine practitioner.

There is in the human mind a love of ease and

indolence which it is very difficult to supersede; it delights to revel in the luxurious listlessness of aught which will save it from the trouble of thought, and therefore it is so much easier to prescribe the same form of medicine for measles, or scarlatina, or typhus, without reference to the peculiarity of constitution, or season, or type of malady, and a thousand other modifying circumstances, than it is to notice the peculiarities of each individual case,—the temperament in which it occurs,—the relative degree in which the several tissues are disordered, and the products of secretion are changed,—the amount of general and local irritation,—the primary disturbance of the system, and the direct and indirect influence of this disturbance upon other organs and functions of the body;—in fact to trace back symptoms to their causes,—to estimate their relative importance and probable influence,—to weigh the effect of remedies already exhibited,—to reason out the indications arising from all these, and many other contingencies,—and then to prescribe for the *individual* efficiently, that we cannot be surprised at the ordinary result. Nothing short of an enthusiastic love for our profession,—a deep sense of the moral obligation to exert our best energies on its behalf,—an accurate estimate of the value of human life, and of the responsibility involved in the care of its preservation,—and a conviction that we are pursuing the good of our patients—not *our own good*—can save us from falling into this form of empiricism, or can enable us to exercise the habits of observation, discrimination, and ratiocination, which will alone preserve us from the engulphing vortex of routinism.

A second form of professional empiricism is to be found in the inert practitioner. The same causes are operating as in the former case, only they are producing a different result, probably according to the constitutional tendencies of the individual so practising. It is exhibited in the method of treating disease, and perhaps in this respect it may be less dangerous than some other forms of quackery, because it leaves more to the agency of nature, and her agency, when neither excessive nor defective, nor misdirected, is essentially conservative. The inert empiric gives himself little trouble in the investigation of malady; he prescribes some very trifle, gives what will do no harm if it effect no good, and under the worst of circumstances quiets his conscience by the reflection that he at least has not destroyed his patient. But this is a fatal mistake—the deep prejudice of lethargic indolence! For the moral prohibition "thou shalt not kill," involves within its meaning the active zealous employment of every possible means for the preservation of life and health, and he who suffers his patient to die from want of activity in his treatment, is as deeply guilty as if he destroyed him by ignorant and erroneous activity; in the one case death is occasioned by withholding the means of recovery, in the other by the administration of ill-timed remedies. Now, this inertness generally arises from scepticism as to the efficacy of medicine, and this doubt leaves the prescriber in so uncomfortable a state, as to paralyse his energies, and to place him spell-bound within a magic circle of listless indifference and hopelessness, having its prototype in the other forms of scepticism, all originating from one common centre,—viz., the want of an *unprejudiced mind*, and the absence of intelligent investigation, with a desire after the conviction of truth.

The incarnation of a third form of professional empiricism is to be found in what is designated the *elegant prescriber*. The real object to be accomplished is entirely lost sight of in the design of directing what will be agreeable to the patient, and the efficacy of the medicine is subordinate to the gracefulness of the *vehicle*.

Another and a frequent mode of empiricism consists in taking partial and even exclusive views of disease. A favorite hypothesis is selected, and facts, and circumstances, and symptoms are so distorted, as to be perverted towards its support. This form of quackery is generally found in combination with splendid talent; indeed it requires the employment of talent to sophisticate truth to such an extent as to give currency to propositions so monstrous! And yet so it is, some favorite organ is fixed upon as being the the source of all imaginable ills, and to it, primarily or secondarily, are referred all the morbid actions of disordered health. In the history of this exclusive pathology, the stomach, the liver, the heart, the brain, the kidney, have all possessed, even within our own recollection, their respective idolatrous votaries, and that, too, among the master-minds of our profession. But they were master-minds over others most perniciously, inasmuch as they imbued the young, the inexperienced, and the unthinking, with most mischievous prejudices; yet they were not master-minds to themselves, inasmuch as they allowed their judgment to be warped by exclusive, narrow, and injurious views—injurious even in their own hands, and destructive in the hands of others who had not the power to discriminate their weaknesses from their brilliance.

Again, the professional empiric is frequently to be found among two very opposite classes,—viz., the semeiologists and the pathologists; the first prescribing only for symptoms, without giving himself the trouble to inquire after the organic causes of those symptoms, almost always, if not always, dependent upon the functional disorder of some one organ of interior life; the second going equally wrong in the opposite direction, exhausting his energies in the vain endeavour to ascertain the precise pathological condition of the disturbed organ, and forgetting the constitutional irritation which is going on, the particular nature of that constitution, its modifying influence upon every local morbid action, and the thousand other circumstances, both extrinsic and intrinsic, which should be brought to bear upon its maladies, and both going wrong in this one particular,—viz., that they have prescribed without due consideration, without the knowledge they might have attained, and therefore empirically.

The love of novelty may be stated as another of the hydra-heads of empiricism. Almost every week—certainly every year—furnishes us with some new method of cure, some new remedy, or some novel application of an old one; and by many these novelties

are taken up, because they are new, with all the ardor of a first love, to be pursued for a time with undiminished attachment, but to be followed, ere long, by disappointment and neglect. Hence it often happens, that that which has been extravagantly extolled, is as unjustly decried, and the real benefit to mankind is frequently lost between the ultra zeal of inordinate attachment, and the cold disdain and frigid indifference which arise from the discovery that such attachment has been misplaced.

Fashionable medicine may be noticed as another empirical product. There are revolutions in medicine which may be termed fashions, and it is the subjection of the understanding to such changes, which it is so difficult to avoid, and which is here so particularly stigmatized. For example, with regard to venesection, we have lived long enough to hear the lancet banned as "that minute instrument of mighty mischief," and extolled as a sovereign remedial agent in almost all kinds and stages of malady, and we have lived to see the successive rise and fall of hypotheses, in which the necessity of bleeding by pounds rather than by ounces has given place to the importance of not abstracting the vital fluid at all, or at all events, in the most niggard quantities; and again, we have witnessed the resuscitation and decline of these antipodes. Happy, indeed, if we ourselves have escaped the trammels of these conflicting errors, and have been enabled to adopt that *just milieu* which it is so difficult to preserve. At the present period, we have been witnessing for some years past, the decline of that heroic system of treatment for which our country has been famous. Our practice in this respect has been miserably extravagant. Re-action was certain of taking place; and so it has been gradually cooling down, till we now witness the rising of another —the study of the natural history of disease—an old acquaintance with a new name; nothing more or less than a revival of "la Médecine expectante," which we venture to predict will be no improvement upon its predecessor; but which will have its fashionable hour, will be only a little less mischievous than the heroic system it supplants, and after inflicting its customary measure of evil, and administered to the glorification of its early patrons and advocates, and disappointed its disciples, and destroyed a moderate portion of human life, will sink into oblivion, and give way to some newer hypothesis, or, possibly, leave behind it traces of rational medicine to enable our successors to advance the healing art some real steps towards practical improvement. Would that we could rely with any confidence upon such a prospect! But we see no signs of such improvement in the cultivation of the human intellect to justify such a confidence.

One other form of professional empiricism is to be found in the adoption, and almost universal application of some *favorite remedy*. Perhaps this remedy shall be a very important agent when rightly and duly administered; and the evil consists, not in the insufficiency of the remedy, but in its almost universal application. This is an error into which enthusiastic genius is very apt to fall; it is delighted with the apparently miraculous effects of the medicine in some cases, and by degrees it extends this agency to other cases, which possess nothing in common with the former, and which, therefore, cannot be benefited, but are in reality *excluded* from the benefit which ought to be derived from a more appropriate treatment. The empirical employment of carbonate of iron—of hydrocyanic acid—of quinine—of cold water—and of various other remedies, will suggest frequent exhibitions of this mode of quackery.

Such then, may be stated as a sketch of the pathology of professional empiricism, and it is doubtful whether any one can plead *exemption—entire exemption* from some infusion of one or other of these evils; some of them arising, as they decidedly do, from the excess of good action and good feeling; yet, be it remembered, that the excess of good is a caricature of evil!

Nor is it wonderful that such should be the case, for we are placed in situations where the demand upon our powers is very great, and the smiles of an approving conscience almost our only reward;—where the public is exacting upon our time, and niggard in its recompense;—and where, therefore, there is great danger lest we fall into *routine* from the positive exhaustion of physical energy, and the listessness produced by unrequited toil! Some have been forced into the profession with total disinclination for its scientific pursuits or its practical details, and therefore become *inert* in action, averse from study, and sceptical in theory. Others have contemplated the injustice of the world, have seen successful manner, and unsuccessful talent, and having no very high idea of medicine, and a most imperious necessity for the means of subsistence, have sought to secure the latter object, by pleasing rather than by benefiting their patients. Others, with the versatility of genius, have so devoted themselves for a time to one particular form of malady, that the idea had become exclusive—they can distinguish nothing but their favorite hypothesis, and they have become veritable monomaniacs! Others, again, are so completely influenced by novelty, that to be new is a sufficient attraction to their minds, and an adequate passport to being accepted as true—to being dearly cherished and highly prized, till the zest has worn off by time, and it is then thrown away as a thing of nought;—while others possess minds so open to fashionable impression, or so easily moulded by favorite hypotheses, or so engrosssed by favorite medicines, that they yield the solid acquirements of talent, and the native inspirations of genius, and lie immolated upon the altar of *fashion*.

And what are the appropriate remedies for these evils? for the knowledge of a disease is more than half its cure, and the only use of rendering prominent these infirmities is, that we might aid in the restoration of the sufferers?

The essential character of all these modes of empiricism consists in a want of the due employment of the reasoning powers, and therefore the appropriate means of cure are to be found in habits of greater self-denial,—of more accurate observation,—of more devoted thought,—of more logical reasoning,—of more enlarged views,—more defined indications,—more solid

judgment,—juster conclusions,—more untiring zeal,—more extensive information,—greater circumspection,—more accurate discrimination, and greater love for the scientific pursuits, and practical duties of every-day life.

A REPLY TO DR. OGIER WARD, RELATIVE TO THE DISEASE, SPASMA GLOTTIDIS.

By John Richard Wardell, M.D., Edin.

"Nonnunquam etiam errorem creat similitudo."—*Cicero.*

"This opinion of his principles (the person who has taken his principles from doubtful propositions,)—let them be what they will—being once established in any one's mind, it is easy to be imagined what reception any proposition shall find, how clearly so ever proved, that shall invalidate their authority, or at all thwart with these internal oracles; whereas the grossest absurdities and improbabilities, being but agreeable to such principles, go down glibly and are easily digested."—*Locke's Essay on the Understanding.*

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,—Since my removal to London, a multiplicity of circumstances have precluded the possibility of any attention being paid to literary concerns, and indeed it was not till last evening that I perused Dr. Ward's paper published in this Journal on the 22nd March, or I should previously have replied to his communication. I now, Sir, however, ask the indulgence of your columns, and beg respectfully in a brief manner to notice certain points in Dr. Ward's paper, in which he specially enlarges upon the doctrines set forth, relative to this affection, by myself, when commenting upon the cases published some months ago. It may here be briefly observed, that after carefully reading over Dr. Ward's paper, the drift of the argument which the writer endeavours, (but I humbly think unsuccessfully) to set forth, is that these cases of my own, to which reference has just been made, as well as similar examples, that subsequently to these appeared in the medical periodicals, were not illustrations of a spasmodic affection, but veritable instances of inflammatory disease,—in other words, of acute laryngitis: this then is the *quæstio vexata.*

"*In my last communication of an obscure case of sudden death, with enlarged thymus,*" says Dr. Ward, "*I alluded to some cases of laryngeal affection, lately published in the* 'Provincial Medical and Surgical Journal,' *by Dr. Wardell, respecting the nature of which I differed from the author; and I stated my intention to return to the subject at a future period, and to describe a case which had recently fallen under my observation, which seemed to me, though identical in its symptoms with Dr. Wardell's alleged cases of spasm of the glottis, to be* PURELY INFLAMMATORY." This case which Dr. Ward goes on to describe, is in the instance of a young woman, precisely the cases in which we observe, most frequently, anomalous hysteria—spasmodic attacks. When Dr. Ward first saw her she was in a semi-recumbent posture, with tumid face, bright and prominent eyes, distended nostrils, gasping for breath, and exclaiming in a whisper she was choking; she threw her arms about, the breathing was stridulous—indeed there were all the manifest symptoms of approaching asphyxia, from, of course, partial occlusion of the glottis, which symptoms *suddenly* came on at four o'clock p.m. Now, Sir, would it be reasonable to suppose—would it be consistent with the views of one but little conversant with pathological and physiological enquiries, to conclude that this immediate seizure at four, p.m., this sudden pain and rigidity in the larynx, were the results but of inflammation? Certainly it must at once be conceded that the inflammatory phenomena never supervene so momentarily. The dyspnœa, the danger, became more and more urgent and obvious; Dr. Ward was afraid to leave her for more than a few minutes, and determined upon laryngotomy. He returns, the patient swallows with much difficulty, so much so as if she had quinsy,—the throat is examined, but *no traces of inflammation are discoverable*, a small quantity of alum is blown into the throat, the patient coughs, a clearer voice is momentarily produced, the breathing at once becomes freer, and the respirations and pulse directly fall thirty per minute! Can Dr. Ward, Sir, or any of your readers seriously affirm, that inflammation, undisputed veritable inflammation, would, under any circumstanstances,—by any agent,—in any organ,—in any tissue, in so sudden, so precipitate a manner supervene, and by the application of a little powdered alum, (this asserted therapeutic action of which I was certainly before ignorant,) be as speedily dispersed?—and could it for a moment be doubted that these were spasmodic and not inflammatory symptoms? Had Dr. Ward, immediately on witnessing this case, (manifestly labouring under partial closure of the glottideal chink,) but rotated his finger freely in the throat, and thus produced a fit of coughing or the efforts to vomit, there is not the least doubt that such expedient would have been followed by as speedy a relief as that which succeeded the alum, for had not the coughing taken place, I fear the employment of the agent would have been inoperative. It has long since been known, and if Dr. Ward will but consult the various writers on the subject he will find it recorded, that the induction of coughing and efforts to vomit, during these dyspnœal paroxysms are highly desirable, they produce relaxation of the muscles proper to the larynx, the air is then freely admitted, and the patient speedily relieved, as in the manner described by Dr. Ward in his example. He also tells us that as soon as the vomiting came on, she was out of danger, (had this vomiting with such celerity reduced the inflammation?) and soon afterwards the countenance became so natural—so free from congestion, that Dr. Ward at his next visit, almost failed to recognize his patient, which forsooth Dr. Ward termed the "subsidence of the fever!" The facial congestion, the prominent eyes, the distended nostrils mentioned in the case, of course resulted from pulmonary obstruction. The author then proceeds to comment upon the case, recounts the symptoms, the sudden affection of the larynx, dyspnœa, loss of voice, stridulous breathing, etc., "*clearly indicative,*" observes he, "*of physical obstruction to the passage of the*

air, while her own description of feeling a thing like a heart at the back of the throat, yet INVISIBLE ON INSPECTION, *points clearly to the epiglottis as the part she meant.*" It is not for a moment doubted that there was physical obstruction, but was this organic or spasmodic—that is the question? If it had been inflammatory enlargement, surely some increased degree of redness would have been observable on the examination of the throat. It may readily be imagined after so severe an attack, such considerable rigidity, such capillary obstruction, as must for the time have been caused in the soft coverings of the parts in question, that a slight degree of swelling would result, which, together perhaps with the functions of the parts not having entirely recovered themselves,—that is, the entire subsidence of the spasm, might give that peculiar feeling spoken of by the patient. But was this heart-like body present before the paroxysm—did she mention this enlargement as it was considered before?

"*It may, however, be objected, that the speedy relief induced by the insufflation of the alum is inconsistent with the removal of an inflammatory deposit such as œdema.*" Certainly it may, and with very plausible reason, as it must appear self-evident, that neither alum nor any other remedy with which we are acquainted possesses such wonderful—such magic properties. From the remote time of Celsus, *heat, redness, pain and swelling*, have been the great pathognomonics of the inflammatory state. Inflammation, properly so called, is a process of change, gradually induced in the ultimate structure of the parts; there is congestion of the capillaries, then comes their inordinate expansion, vascular obstruction of the larger vessels of the organ or tissue, effusion of serum into the interstitial cellular tissue—hence swelling—and how is this swelling removed when it spontaneously disperses as in a case of œdema of the glottis?—is it not by absorption—that slow and gradual process which amongst others nature institutes to work her own cure? It would indeed be difficult to reconcile us to the idea that powdered alum, blown on the surface of a part, would so speedily check the progress of these phenomena—remove instanter their results. By a parity of reasoning Dr. Ward speaks of the inflammation of the eye-lids producing œdema, and of the celerity of its declension. Various applications, used to these parts, we are aware, soon remove inflammatory vascularity, by of course constringing the minute vessels, and alum possesses this property; but such is not effected momentarily, and the swelling in these instances must be removed by absorption—a process as we have said, that is gradually performed. Œdematous enlargements in soft parts, as in mucous and cellular membranes, will of course much more readily subside than in more dense tissues, yet they will not disappear, in that summary manner, which they ought to do, for Dr. Ward's doctrine to be at all tenable.

"*I come to no other conclusion than that the above was a case of acute laryngitis, with œdema of the glottis and epiglottis.*" From what has been said,—from the very inconvenient facts related in the case, and which indisputably rather tend to an opposite way of thinking,—from a recollection of the momentary supervention, and the instantaneous relief,—the celerity with which the symptoms disappeared,—the kind of individual in whom the affection occurred,—the non-visibility of any inflammation in the throat when examined,—and, indeed, on a general review of the case, the cited opinion becomes exceedingly problematical, and is a very sweeping one, to which many other impartial judges would not subscribe. Dr. Ward has made this assertion, and without doubt from a self-conviction of its truth, but with others it appears to want the corroboration of incontestible proof, which is certainly not supplied by his history and treatment of the case.

"*Dr. Wardell sets out by stating that 'these cases are not published as presenting features of very great rarity;'—'that spasm of the glottis is but occasionally met with in adults;'—'nor was it until of late years fully understood.'*" In further explanation here I may say that, when I looked over the series of cases, which the Editor of this Journal has done and is doing me the honour to publish, I was conscious that none of them were *very* uncommon examples of disease, which some writers erroneously imagine are alone worthy of being recorded, like as we sometimes see students give the greatest importance to witnessing a grand operation which during their whole lives they may never be called upon to perform, whilst many other interesting specimens of disease, and which they may be called on now and then to treat, are unheedingly passed by. They were not published with an idea of the fallaciously conceived merit of extreme infrequency, but as examples, the pathology and treatment of which are not so satisfactorily established as of many other complaints, and reasoning from the diversity of opinion which have called forth these remarks, the affection by whatever name we may please to call it, is not ineligible for being placed in a permanent form.

"*That such cases are not very rare we may judge from the numbers that have recently been published in the medical journals since Dr. Wardell has turned his attention towards them.*" Now, Sir, I opine that a disease may, in the general acceptation of the term, be *rare*, notwithstanding that several instances may be supplied from individuals who have perhaps passed a long life in practice, and over the populous districts of this country, where, happily now, the journals of the day find their way into the remotest parts;—I repeat a disease may be rare, though several examples are supplied out of thousands of practitioners, and from millions of population. Let Dr. Ward, or any of those who may chance to peruse this letter, but ask themselves how many cases have occurred to themselves, and the answer must be in a paucity of number; have they met with one even in two years—in three years—in five years?—however, generally speaking, it is an uncommon affection in the adult.

"*I would beg to be informed where we can meet with published cases of pure uncomplicated spasm of the glottis in the adult, as I have not been able during an extensive research, especially directed to this subject, to meet with a single instance.*" Sir Henry Marsh has written upon the disease; and if Dr. Ward will refer to the "Encyclopædia of Practical Medicine," he will be enabled to find instances. Dr. Locock, "On the Nervous

Diseases of Women," mentions an example; and my friend Dr. Browning Smith, of Kensington, has favoured me with an indisputed case, and on discussing the point with that gentleman, from whose talent for observation and extensive practice I have the greatest confidence in his opinion, Dr. Smith was decidedly convinced that you may have pure uncomplicated spasm. Let me cite the Doctor's case:—

"November 8th, 1847. At half-past six in the morning I was called to Earl's Court, Brompton, to see a lad, aged 15, who was reported to be dangerously ill; the bearer of the message said 'they thought it was croup.' I hurried off immediately. On arrival, the breathing was laborious to an alarming degree, and each inspiration performed with a crowing sound, so extremely difficult was the function carried on, that there was evidently some risk of suffocation; the countenance was red and flushed; eyes starting and ejected; pulse quick; and the greatest suffering depicted in the face. Each paroxysm continued for more than a minute, when there was an intermission, but during these intervals the breathing was still performed with great pain, and the stridulous noise was still audible. They had given him brandy, because in two or three similar attacks which he had had during his life, ardent spirits had been at once followed by relief; this time, however, the brandy had not the desired effect, while the symptoms assumed a graver character, when they hurried off for medical advice. I gave him immediately a large dose of sulphate of zinc, which readily produced vomiting, and as soon as ever retching was produced, the breathing was at once and permanently relieved. In the evening when I called he was well, prosecuting his ordinary occupation, and required no further attention."

"I may here observe," continues Dr. Smith, "that about this time, rather remarkable to say, I saw three cases of that dangerous disease, (acute laryngitis,) all in adults, in each the symptoms came on *gradually*; it was *by degrees*, not all at once, that the disease assumed its alarming characteristics. In the first instance the disease had proceeded to some extent before the patient sought advice, and this person died. The breathing was not so very much—not so paroxysmally affected, as it was in the case of spasma glottidis above-mentioned; the voice became husky, no loud crowing sound when breathing, but occasional paroxysms of dyspnœa, and the patient by degrees sank from an asphyxial condition of the lungs. In the second case pretty similar symptoms were manifest, but in less degree of intensity, and the individual recovered. The third case went on, in despite of every endeavour, to a fatal termination. I managed to obtain an examination of the throat, (I ought to have observed above, that as a last resource I performed tracheotomy,) when effusion of pus, and a distinct false membrane, were abundantly discoverable, as also an œdematous condition of the whole of the lining membrane of the larynx. In my own person some years ago I was subject to spasm of the glottis, and thus singularly enough happen to have experienced the disease myself. I was very properly treated by stimulants and antispasmodics."

Before proceeding further, was not the example of the lad of Earl's Court, beyond the shadow of doubt one of spasm of the glottis?—could a better example be given of it in a "pure and an uncomplicated state?" Could any one for a moment have deemed this inflammation? Compare then, Sir, the cases of indisputed inflammation of the larynx with that—where the symptoms *gradually progressed*—in which there were paroxysms of dyspnœa, but no loud trumpetty crowing,—in which the real danger was greater than the symptoms seemed alarming, and we are compelled to acknowledge there *was* a difference, and this consisted in the difference between inflammation and spasm. As an argument like the present, which has been thought to admit of dispute, cannot be too strongly maintained, I may here briefly cite an instance that now occurs to my recollection of a patient in Edinburgh, under the care of the late Professor Graham, during the time that I was physician's assistant in the hospital. One Sunday just before the visit at noon, the nurse ran, in a state of considerable excitement, to one of the clerks, saying that one of the convalescents from fever was dying. Before I arrived one of the other gentlemen was in attendance, and when I reached the ward the patient was still labouring under a frightful attack of spasmodic breathing; was crimson in the face, (not from inflammatory fever;) the eyes were starting; the pulse considerably accelerated; and he seemed as if about to suffocate. Aapplications externally, and a large dose of æther, soon removed the symptoms.

"*There are numerous cases of dyspnœa, spasmodic asthma, and angina pectoris in our medical records, and every man of experience can doubtless add to their number from his own practice; but pure spasm of the glottis is not met with in adults in England, whatever may be the case in the north.*" Dyspnœa may arise from many causes, and is, properly speaking, but the symptom of diseased conditions, and not the conditions themselves. In spasmodic asthma the affection is located in the bronchi, not in the larynx, and if the stethoscope is applied to the lateral aspect of the larynx, the peculiar sound, as of air rushing as if through a narrowed aperture, is not heard. Angina pectoris is a disease of the heart or its great vessels—not of the throat. That pure spasm of the glottis *is* met with in England, the cases of Drs. Laycock and Smith, as well as those of Messrs. Gorringe and Alford, and in my own humble opinion those recorded by myself, attest.

Dr. Ward proceeds by making condensed observations on the two cases which have given rise to this letter. In the case of the girl Cooper, as mentioned in the history of her affection, cold and wet were undoubtedly exciting causes, and they are calculated to be so in the spasmodic affections of other parts as well as the throat; nor is it inconsistent with, nor does it at all militate against, the doctrine now endeavoured to be maintained that they should. Mr. Gorringe, Surgeon to the Cornwall Infirmary, (to whom I have above incidentally alluded,) after the appearance of my own, sent a case, as he thought, "fully corroborative of the remarks" which I had offered, and if Dr. Ward will have the kindness to refer to the example given by Mr. Gorringe, he will find that Caroline Sampson's attack

"came on suddenly, accompanied with a crowing noise, and dreadful sense of suffocation." Mr. Alford, of Tewksbury, who reported the other illustration confirmative of the views taken, is particular in noticing the suddenness of its supervention. "October 15th. This morning at six o'clock I was called in great haste to him," says Mr. Alford. "His friends informed me *he was very well until just before they sent.* He had not been to bed, but stayed up all night with them previously to his going to his place as a servant, and just as he was leaving the house with his bundle, *he suddenly complained of difficulty of breathing, and was taken 'in a fit!'*" The question before asked is now made in repetition, did the illness of either come on like inflammation? The latter was, we see, in the person of a healthy farm-servant, who was momentarily seized when with his bundle on his back he had left to repair to his new situation. Who ever heard of acute laryngitis without any pulmonary symptoms,—without any warning, coming on like a fit? And to what physiological and pathological principles can Dr. Ward possibly have recourse, in his maintenance of the inflammatory theory.

My opponent in opinion mentions bloodletting which was had recourse to in the treatment of Esther Cooper. I may here say that I did not see the patient in her first paroxysm; nor do I say that I should have bled her, as in the subsequent attacks, which were as violent as the first, the induction of efforts to vomit readily restored the inspirations. Mr. Cole, however, with a fearless and active decision, when he saw the imminence of her situation, resolved to overcome the rigidity by a free use of the lancet—the most potent and effectual of all methods in the induction of speedy relaxation. It is a fact, demonstrated in the practice of medicine, and an unwelcome fact, that the proofs of practice are often at varience with plausible theory and refined speculation, and thus often in our most certain anticipations we are doomed to disappointment. An eminent Professor here observed to me the other day, that if we endeavour to account for all the phenomena of disease, and the means by which they are cured, we shall often be perplexed and at fault. We do not at *all* times bleed with a view to the existence of inflammation; the use of the lancet is not ever the sign and symbol of that diseased condition. If reference is now made to the remarks offered relative to Martha C——, it will be seen that under a consciousness of the non-existence of inflammation, I freely bled her, and thus when large, very large, doses of opium and other antispasmodics had failed, overcame the rigidity. As to the boy John P——, Dr. Ward either mistakes or there is a misprint—not eleven days, but two days intervened between his hoarseness and his seizure, and mind in this interval he was well, and pursued his wonted occupations. I bled him, but with a reference to the lungs, to restore those organs to their function, decreasing the congestion, and thus at the same time relieving the tightness complained of in the thorax, and the blood which first flowed as mentioned was thick and tarry from non-aeration. Still touching upon this lad, Dr. Ward says:—"*It (the spasm,) afterwards returned with violence, and was attended with convulsive movement of the limbs, and hard accelerated pulse, the patient being an epileptic subject.*" The returning with violence was of course characteristic of a spasmodic disease; we do not observe the pain and disorder produced by spasm, remain at one degree of intensity—nor is it continuous; indeed I have always been led to form my diagnosis of these respective diseases, chiefly by the steady, less urgent, but persistent pain of the one, and the paroxysmal intense pain of the other; hence these returns corroborate the opinion entertained that it was spasm. As to the convulsive agitation of the limbs, we are aware that impeded circulation in the encephalic mass, the pressure thus produced upon the central organs, the baneful effects which an impure instead of a healthy arterial blood circulating in the system must produce on the nervous system, are conditions highly predisposing to convulsive action; and most of all, the *pressure* thus given rise to in the brain, the rationale of which I have endeavoured to give in the observations, appended to case No. III. of the series. As to the excitement of the pulse, was it not sure to rise under the oppressed action of the heart, the great and laborious fatigue induced by the difficulty of breathing? Certainly, it could not be otherwise, and as soon as ever breathing was restored and the heart's action rendered freer, the pulse became more natural; and in Dr. Ward's own case, even so sudden was the relief and change in its frequency, that it actually fell thirty beats in the minute. Lastly, may concisely be noticed, the question—was it epilepsy? Dr. Ward must recollect that foaming at the mouth, convulsive twitching of the face, complete loss of intelligence and total insensibility are the pathognomonics of epilepsy, but in neither of my own cases, nor in any of the others here mentioned, were such to be noticed. The girl Cooper, had never had any description of fit during her existence, and the boy whom I saw previously, in an epileptic fit, was then differently affected. He fell down suddenly, had foaming, twitching of the face, eversion of the eyes, was quite sensible, had no croupy breathing; in the attack of spasm he was not struck down, nor were there any of the cardinal symptoms of epilepsy.

"*Now, in regard to these cases, both of which were attended with febrile symptoms at the outset, &c.*" We cannot, with any fair show of reason, as above insisted, say, that because there was flushing of the face, prominence of the eyes, an excited circulation, produced by the conditions of obstructed circulation, and the fatigue and excitement given rise to by such state,—the closure of the glottis,—that they were anything more than of a transient character. The history of the case, the crowing respiration, a review of the symptoms generally, ought, without doubt, to have led to the correct decision.

"*Dr. Wardell must be aware that true spasm or closure of the glottis, from whatever cause, cannot continue for more than a few seconds, without being followed by death.*" Such statement is self-evident as ever was Euclidean proposition. Without doubt, perfect closure of the glottideal fissure by spasm, if continued, would kill with as unerring certainty as if the patient were bow-strung, or suspended by a cord. Dr. Ward

cannot for a moment suppose that the chink was entirely—wholly—closed; of course, when speaking on the question, it is presumed there was slight room for ingress of air, or how does that gentleman account for the crowing? does not such result from a narrowed aperture, or are we given, by the foregoing quotation, to understand there was no space left for the admission of air at all? Surely this cannot be the doctor's meaning! Any further observation on this part of the question would indeed be superfluous.

"*It would have been better had he imitated the reserve of that excellent pathologist, Dr. Copland, who does not admit any disease under that name in his Dictionary of Medicine.*" It would indeed have been utter presumption on my part to have given a nosological term to a disease which Dr. Copland could not satisfactorily do. From this it would appear, that Dr. Ward is not aware the affection has long since been written upon under that appellation. I certainly lay no claim to the honour of thus naming it, and if the writer of the objections to the term will but turn to the head in the "Encyclopœdia of Practical Medicine," he will there find it so called. One cannot but respect Dr. Ward's reverence for great names—for great book-makers; and the *ipse dixit* of one who has written so voluminously as Dr. Copland, without dispute, meets profound attention; yet, notwithstanding, we are not always to be dissuaded from giving evidence to ocular facts,—to things entertained as true from downright conviction, because lettered celebrity may have been of another way of thinking; for even the most accurate inquirers are not infallible in their conclusions. We are not always to put implicit confidence in an opinion merely because it is the general notion, and has the warrant of ancient usage; if so, many sophistries, long exploded, would have now remained to fetter the progress of science;—then Bacon had never pointed to posterity the path to truth; Galileo had not dared to question the doctrines of ancient sages, nor Newton presumed to overthrow the Cartesian philosophy. Have not recent years and mediocral men shown, that the great Cullen, who has been justly ranked amongst those who are accounted the most eminent benefactors of our race,—have they not shown that his theoretically well arranged nosology is not always consistent with nature? It is this dispute about words which has so often led to error, and it would be well to remember the aphorism of Quintilian, "*res non verbis in quæso*;" and the saying of the renowned lexicographer, Johnson, that "human experience is the great test of truth."

"*Dr. Wardell has failed in his endeavour to prove the existence of any hysterical affection in either case, in support of the spasmodic character of the attacks.*" When it is considered that the girl Cooper was a young female of chlorotic appearance,—that the catamenia had not been regular,—that the boy was about puberty,—that hysteria does at times appear in the male at that time of life,—that between the affections of the two there was a decided similarity,—that of all other diseases, hysteria is the most Protean,—and that hysteria is avowedly morbid change in the nervous system, to which system we alone refer spasmodic diseases, the opinion cannot be deemed as wholly untenable. In Mr. Gorringe's case, and in that of Martha C——, both were chlorotic patients, and of course highly predisposed to anormal nervous affections.

"*I cannot but object to these cases being brought forward as instances of it, particularly as they have led to the publication of similar ones by other parties, to which the above remarks are equally applicable.*" Such are the words of the writer in his terminating remarks, yet before concluding, I would ask Dr. Ward if, on a calm and deliberate review of the question, he can seriously persist in the opinion which he has made an essay to maintain,—if he have satisfactorily proved that spasma glottidis is either a *mis-nomer*, or a term inconsistent with the phenomena of the disease, and that the complaint instead of being a nervous disease, is one of veritable inflammation? In repetition, I will again ask, how does he mean to explain away the suddenness of the supervention and decline. Taking his own ground upon which he stands—his own case—how was it that example (the history of which he has given,) with such celerity was affected, and with such magic suddenness was relieved? Is an inflammatory disease ever, under any circumstances, in any part—any organ, any tissue, thus momentarily developed and momentarily dispersed? If alum or any other remedy could thus instanter remove swelling, in fact drive away, as if by the enchanter's rod, the inflammatory state and the inflammatory results, could this removal of enlargement be, as before enquired, by acting upon the absorbents proper to the part or parts in question? how did it produce the desired—the ready effect?—and did this change, of wondrous celerity, from even suffocation to easy breathing—this restoration of voice—return from peril, the contemplated need of tracheotomy, to safety—the lowering of the pulse,—I would ask, I repeat, if these facts, when reflected upon, without favour or bias to one or other mode of thinking, divested of pre-supposition or pre-conceived theory, would they incline to the notion of acute laryngitis? If the disease were one of the inflammatory order would the stimulant, the brandy, the antispasmodic treatment which in the cases above mentioned were of such benefit here prove effectual?—would the mere indication of retching and vomiting have in a trice settled effusion? Why, then, need Dr. Ward "object," seeing that the treatment was based upon correct notions of the pathology—I repeat correct—from the above assertions, and the results of the remedies employed—object to doctrines which I humbly think he has signally failed to disprove. Whoever heard of brandy curing laryngitis?—yet the lad mentioned by Dr. Smith was cured by it. I say *cured* in this instance, though it is a term often employed, without the warrant of fact. It might, I think, be "objected," if all entertained the notions of Dr. Ward respecting its pathology; and would *certes* seem very odd to cure acute laryngitis by stimulants—antispasmodics—by brandy and water!

I must apologize, Sir, for having thus replied so much at length, and at the same time must observe that the numerous readers of your valuable pages cannot but feel indebted to Dr. Ward, that he has

enquired into a subject meriting attention; and although I have advanced statements opposed to his views, I have no doubt Dr. Ward has given what was but his conviction, and in the laudable endeavour for the elicitation of truth; nor can such spirit of enquiry become too common, amongst those who practise our difficult art. It is this desire for research—this determination to look into and examine, by which alone false reasoning is to be unveiled, and error detected; and thus prejudices dispersed, nor doubtful propositions taken for principles. The words of a great philosopher may here, in conclusion, be cited, which, with too much truth, often obtain. "The first and firmest ground of probability is the conformity anything has to our own knowledge, especially that part of our knowledge which we have embraced, and continue to look on as principles. These have so great an influence on our opinions, that it is usually by them we judge of truth, and measure probability to that degree, that what is inconsistent with our principles, is so far from passing for probable with us, that it will not be allowed possible."

I am, Sir,

Your obedient servant,

JOHN RICHARD WARDELL.

ON THE

MEDICAL AND GENERAL TREATMENT OF LOCAL DISEASES, IN PREFERENCE TO THE TREATMENT BY OPERATION.

By Thomas Hunt, Herne Bay.

In the earlier days of surgery, the dread of "the knife" on the part of the patient, and the timidity of the surgeon—at that period only half an anatomist—presented a more than sufficient check to the undue practice of operative surgery; and if the improved anatomy of modern times has removed one objection, the pain attending the severer operations has, till recently, presented another obstacle to their too frequent performance. That obstacle, however, appears likely to vanish under the very general use of anæsthetic agents, and there now remains no objection to operative surgery, apart from those considerations which regulate all medical treatment,—viz., its disadvantages and dangers, as contrasted with its advantages or necessity. There are indeed many operations, the propriety of which can only be determined by the last-named question,—viz., their urgent necessity. Some of these may be highly dangerous, extensively mutilating, or even doubtful in their results; yet, if they prove the only alternative between life and death, their performance, at some risk, may be justifiable. Other operations may be advantageous and eligible, though not absolutely necessary to life, or even to the recovery of the patient. All these questions are, by the common consent of the profession, referred to what are called the established "principles of surgery." Many of these principles, and much of the practice of modern surgery, together with the views of the nature and treatment of local disease, which prevail in our hospitals and infirmaries, are of *recent origin*. A large proportion of them are regarded as among the improvements of the present century; and as many of the views of the eighteenth century have been exploded in the nineteenth, those of the present day may be destined to yield to the rapid advance of science, and to be exploded in their turn. The principles of surgery are still therefore entitled to veneration, only so long as they can be shown to be founded on the most advanced discoveries of medical science; and as medical science is still in its infancy, (seeing we have yet to learn the nature and phenomena of inflammation, the rudiments both of disease and of recovery,) a calm and practical inquiry into the necessity and propriety of certain operations of daily occurrence, can never be deemed unseasonable or preposterous.

The object of the writer of these remarks is to *promote* such an inquiry among the members of the Association. The facts which he proposes to bring forward will not be adduced in order to support sweeping assertions or dogmatic inferences on his own part; they are rather intended to elicit from the members other facts, either of a similar or contrary tendency, and to invite discussion on a subject which has as yet been treated with perhaps too much tenderness and reserve. It is much to be regretted that those members of the profession in whose hands the operative department is chiefly placed, are not as yet required by law to possess a knowledge of those higher principles of our art on which chiefly the propriety of operations must be decided,—viz., the powers and limits of medical treatment. That many of the "pure" surgeons of the day, as they are called, are well acquainted with pharmacy, medicine, and general therapeutics, is rather a happy accident than a matter of course; yet with these, medicine, often despised, is always regarded as a minor object of study. The physician is seldom called upon to apply the resources of his art to the treatment of local diseases affecting the external organs of the body; and if the general practitioner is required to be instructed in both these departments, it may be said that surgeons are too generally entrusted by the public to determine the propriety of severe operations in the inverse proportion to their *legal* qualifications for so important a function. The result which might be *expected* from this arrangement is, *rashness in operating*. Whether this result has been realized to any serious extent, is a question of momentous import,—a question which must sooner or later undergo a professional scrutiny of a severe and searching character.

The subjects to which this inquiry is applicable are as numerous as they are important; they are dispersed over the entire surface of surgical science, and in their

selection for discussion, regard will be directed to their magnitude in relation to the preservation of life, rather than to the difficulty of their performance.

I. Strangulated Hernia.

The efficiency of a skilful and persevering employment of the taxis, in preference to the division of the stricture by the knife, has already been partially discussed in the pages of the *Provincial Journal*. No less than four correspondents, (none of them novices in surgery,) have by their united testimony made a very trong case against the frequent performance of the operation. It has been demonstrated, as far as demonstration is applicable, that by the taxis alone, conducted on principles based on anatomy and physiology, and continued *for a much longer period than is advised in any standard work of surgery*, a strangulated hernia may be reduced long after the occurrence of symptoms which, in the opinion of the best authorities, would not only indicate the urgent necessity for a division of the stricture, but would interdict all further manipulation of the tumour as a mischievous and hopeless expedient,—as a wanton trifling with the patient's life. And not only has the plan succeeded once by a lucky chance, but in the hands of all the four correspondents above alluded to, *it has never once failed*. As yet no writer in the Journal has ventured to impugn the practice, or to say one word in justification of the prevailing plan of operating in every case presenting trifling difficulties in reduction. The question should not, cannot, rest here. The operation for hernia is full of dangers. Simple and easy in its performance, it too frequently fails to save the patient's life to justify its hasty or indiscriminate adoption. On the other hand, the gentle and patient employment of the taxis is attended by no danger whatever; the force applied to the tumour is regulated by the principle of hydrostatic pressure, and is no more likely to bruise or inflame the contents of the tumour, than pressure upon the projecting membranes of the parturient uterus is liable to bruise the fœtal scalp, surrounded as it is by the protecting liquor amnii. It is, indeed rare, that the pain of a strangulated hernia becomes sensibly increased by a discreet application of pressure to the tumour, even if inflammation has already taken place. All inflamed surfaces are relieved by the steady application of equally diffused pressure. The unduly dilated blood-vessels are supported and sustained, the venous circulation is promoted, and the increased action of the arterial capillaries is checked and confined to definite limits. The fluid contents of a hernia are admirably adapted to regulate and diffuse the pressure from without. Every part of the tumour must receive an equal impulse from any degree of pressure which tends to contract its bulk, and so long as the circulation is going on in the solid portions of the tumour, pressure from without *must take effect upon the veins*, reducing their bulk, and at the same time checking the force of the entrance of blood by the arteries. The wonder is, not that the taxis should succeed occasionally in cases condemned to be operated upon, but that it should *ever fail to reduce a recently-protruded hernia.*

(To be continued.)

EXTRACTION OF A NEEDLE FROM A CHILD UNDER THE INFLUENCE OF CLOROFORM.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,—Presuming that every additional information relating to the practical application of chloroform will be interesting to your readers, I have forwarded the following case for insertion in your Journal, as early as may be convenient.

I am, Sir, your obedient servant,

GEORGE MOORE.

Moreton-in-Marsh, May 24, 1848.

On the 1st instant, at five o'clock, p.m., I was summoned to a child of this town named Wright, aged two years, who was evidently suffering great pain, crying violently (as his mother informed me he had been,) during the whole of the day. This she now attributed to a swelling of the abdomen, which she had just discovered. Upon examination, I found a slight projection of the integument, immediately below the umbilicus, beneath which a hard pointed body could be felt, by pressing upon which the child's sufferings were much increased. Having, in consultation with a professional friend, determined to remove the foreign body while my little patient was under the influence of chloroform, forty drops of that fluid were sprinkled upon a lawn pocket-handkerchief, which was placed over his mouth. A few inspirations sufficed to produce a state of anæsthesia. I then cut down upon and extracted, by means of a pair of forceps, what proved to be a rusty needle, about two inches in length, the point of which was directed to the surface of the body. The child remained insensible during the operation, and for several minutes afterwards. When the wound was dressed, I sponged the child's face over with cold water, which caused him to stretch himself, and rub his eyes; but he immediately sucked his thumb, his usual custom when going into a natural sleep, in which he coutinued for four hours. He passed a good night, and has since had no unpleasant symptoms. The wound healed by the first intention. Nothing is known as to how the needle reached its unnatural position.

The struggles of children frequently present formidable obstacles to operative proceedings of any kind, and when incisions have to be made in important regions, may lead to dangerous results; such would very probably have been the case in the above instance, but for the use of chloroform. The transition from a state of anæsthsia to one of natural sleep, without an intermediate state of consciousness, was most singular. When the child was asked on the following morning "where they cut him," he pointed to a finger which had been cut two or three days previously to the operation. Altogether the effect of the chloroform was most gratifying, as not the slightest ill consequence ensued from its exhibition.

THE RHONCHUS CREPITANS REDUX.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,—Having for a length of time been practically acquainted with the circumstance of the occasional absence of the rhonchus crepitans redux during the return of an hepatized lung to its healthy condition, I have been somewhat surprised to find that this 'fact,' has so long escaped the reading and observation of Dr. Ranking, as seen in the remarks appended to the case of pneumonia detailed in the current number of the Journal. Dr. Ranking having referred only to Dr. Graves' work, may be under the impression that this 'fact,' is mentioned by no other writer. This being probably the case, he will perhaps allow me to call his attention to the following quotations from Drs. Stokes and Copland. To Dr. Stokes' work on "Diseases of the Chest," I was myself first indebted for the information; since which time I have become practically acquainted with the circumstance.

"Laennec has stated that the resolution of solidity is invariably announced by a return of the crepitating rale, (ronchus crepitans redux,) but my experience is altogether opposed to this statement, for I have often observed the change from complete dulness of sound and bronchial respiration, to clearness and return of respiratory murmur, without any crepitus of resolution; and this may be seen in all varieties of pneumonia, nor does the absence of the phenomenon necessarily imply a rapid resolution, for it may be absent in cases in which weeks elapse before the dulness of sound is removed."—*Dr. Stokes*, pp. 325 and 6.

"But a change from complete dulness and bronchial respiration to clearness and return of the respiratory murmur, without any crepitus of resolution, may take place."—*Dr. Copland's Dictionary*, part 8, p. 768.

As Dr. Copland, though using very similar language to that of Dr. Stokes, makes this statement on his own authority, we may conclude that he has himself noticed the circumstance alluded to, and hence considers it an essential part in the history of pneumonia; but to Dr. Stokes, as far as I am aware, we are indebted for first calling in question the dictum of Laennec, that "the resolution of solidity is invariably announced by a return of the crepitating rale."

I am, Sir, yours very obediently,

Manchester, May 19, 1848. B. D.

I am obliged to the author of the foregoing letter for thus correcting my error of supposing that Dr. Graves alone had alluded to the circumstance; in entertaining this opinion my memory had played me false, as of course the writings of the two eminent physicians above-mentioned are not unfamiliar to me. I still imagine that as the non-occurrence of this stethoscopic phenomenon during the resolution of pneumonia, is not mentioned by a public lecturer and practical physician of the eminence enjoyed by Dr. Watson, it must be so rare an event that though B.D. may have been "long practically acquainted" with it, he cannot have met with many examples. I need not say that I speak of the consolidation of *acute pneumonia, the resolution of which follows speedily.* In those cases of imperfect recovery from pneumonia, in which a portion of the lung remains solidified for a considerable length of time, (one of the instances, for example, of *Nature's cures,*) I am quite aware that the lung may recover itself under appropriate treatment, without the presence of any signs to mark the improvement, except the gradual substitution of pulmonary for bronchial breathing. Such a case is in fact at this moment under my supervision.—W.H.R.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, JUNE 14, 1848.

The more closely we examine into the subject of medical relief to the sick poor, the more confirmed are we in the conviction that no real and permanent good will be accomplished until its administration is placed entirely under the control of some qualified and responsible public officer. The Boards of Guardians are, under present circumstances, obviously unfitted for it; for, however intimately local connections may make them acquainted with the condition of the sick poor, their interests are so bound up in keeping down the expenditure, that both the poor and the medical attendants become the victims. On the one hand the medical man is so inadequately paid, that the sick poor are attended and taken care of almost entirely at his expense; on the other, the necessary adjuncts to medicine are frequently witheld, or granted so ungraciously, as to trammel the medical officer in his requirements, and often to render it a personal obligation conferred upon him, that his orders for appropriate diet are complied with. Take, for instance, the following resolution now before us, recently come to by a Board of Guardians. We withold the name of the Union and our authority for obvious reasons.

Resolved.—"That the Board having noticed the very great increase of expenditure in medical orders with respect to meat, porter, &c., beg to call the attention of the medical officers thereto, with a view to the means of diminishing the same, if practicable."

The inadequacy of the salaries of the medical officers needs no illustration; but we may refer to a document just issued by Mr. Garlick, of Halifax, whose energy and perseverance in the exposure of the workings of the present system entitle him to the gratitude of his medical

brethren generally. From this document it appears that in the Halifax District, with an area of 990 acres, and a population of 19,881 inhabitants, the number of orders for medical attendance from the relieving officer during the twelve months ending May 20th, 1848, was 851; the number of visits paid to the residences of the patients was 2612, and the aggregate number of mixtures, pills, powders, lotions, liniments, boxes of ointment, and plasters dispensed, amounted to 19,287. "The remuneration for this duty," says Mr. Garlick, "stands thus"—

"For attendance upon 851 cases of sickness in the Township of Halifax, including Highroad Well, Pellon, and Trafalgar, as per order from the Relieving Officer —for making 2612 visits in the treatment of these cases—and for supplying the amount of medicines above enumerated, the award at present is £80, or 4s. 4½d. per diem.

"The item of medicines alone" he continues "is one of considerable magnitude, and the house of the medical officer whose duties compel him to distribute them in this way, is no longer a private establishment but a *Public Dispensary*. Moreover, if the medical officer think it necessary to apply half-a-dozen leeches in the treatment of any case, he must give the patient half-a-crown out of his own pocket in order to procure them. Can any man be surprised that this circumstance should altogether prohibit the use of leeches in Poor-Law practice?"

The calculation may be made another way. The salary we are informed is £80—that is, 19,200 pence. The aggregate of medicines, &c., supplied, is 19,287, allowing rather less than a penny for each mixture, pill, powder, lotion, &c., dispensed and supplied. Will any one assert that the materials can be purchased in the gross for the sum at which they are here retailed, leaving out of the question the time consumed in their preparation and dispensing? Is it to be wondered at, if in some rare instances, men of limited means, as the medical officers of unions frequently must be, should be unable to supply costly medicines, and be almost compelled to substitute others of less efficiency?

It has been proposed to establish union or district dispensaries for the supply of the requisite medicines and appliances, ordered by the medical officers. Doubtless such a plan might relieve the medical officers from the positive loss which a conscientious discharge of their duties now so commonly entails upon them, but without attributing to the Boards of Guardians more of that moral obliquity which clouds the mental vision of mankind in general where pecuniary interests are concerned, we fear that the same short-sighted policy would be introduced into these establishments which disgraces the present arrangements for supplying medical relief, and that drugs of very inferior quality would encumber the shelves of the dispensaries, as there is but too much reason to believe, that a false economy in the purchasing of them, would be the main principle consulted.

The only inference that we can draw from these remarks is, that the entire department of the medical relief of the sick-poor must be placed in the hands of persons better qualified to judge of what is requisite, and less immediately interested in reducing the expenditure to the lowest possible limits, than the Boards of Guardians, as at present constituted, can ever be.

Reviews.

Principles of Medicine: comprising General Pathology and Therapeutics, and a brief general View of Etiology, Nosology, Semeiology, Diagnosis, Prognosis, and Hygienics. By CHARLES J. B. WILLIAMS, M.D., F.R.S., Fellow of the Royal College of Physicians, Professor of the Principles and Practice of Medicine, and of Clinical Medicine, and First Physician to the Hospital, University College, London, &c., &c. Second Edition, considerably enlarged. London. 1848. 8vo. pp. 533.

This new edition of Dr. Williams' justly-estimated work on the "Principles of Medicine," is, as the title page states, considerably enlarged, containing about one fourth more matter than its predecessor. The additions, as we are told in the preface, are chiefly in the following subjects:—Mechanical, chemical, and dietetic causes of disease; defective cleanliness, ventilation, and drainage; the tabular views of the elements of diseases; reflex action and sympathy; elementary changes in the blood; congestion; determination of blood; inflammation; degeneration of textures; cacoplastic and aplastic deposits; and the whole chapter on hygienics. As this last is an entirely new portion of the work, we shall direct attention in what follows to the opinions of Dr. Williams on the questions embraced in it.

Hygienics are defined to consist in "the knowledge and application of those means by which the structures and functions of the body may be kept in that normal state which conduces to their continued welfare—that is, in *health*." The chief circumstances which promote this condition, on which the author gives in succession brief details, are:—food, clothing, temperature, air, exercise, mental occupation, sleep, and excretion. We shall chiefly notice the first of these heads, though the limits to which Dr. Williams is necessarily compelled to confine himself, prevent more than a mere indication of his opinions being given. Some of these, however, as coming from a metropolitan physician of eminence, may not be uninteresting to the provincial

practitioner. With the objection to the use of brown bread, so much recommended by some high authorities, we are quite disposed to agree. "Very white bread," he observes, "is objectionable, as being less nutritious (having less gluten,) and more constipating, than that made with less refined flour: but the coarse material, commonly sold as brown bread, errs to an opposite extreme, in containing a bran so coarse as to be irritating to many stomachs." In the following observation, with respect to the digestibility of different kinds of meat, we suspect theory has been allowed more than its due weight. "The kinds of animal food," he remarks, "vary much in their composition, even when the lean parts only are selected. Thus, beef and pork contain a large proportion of fat; mutton somewhat less; veal still less; and, in the flesh of fowl, game, and white fish, there is only a small amount. This affords an explanation of the fact, that the latter articles are the best suited to persons of weak stomach." We have yet to learn that this is a correct expression of the fact assumed, or that veal is more suited to the weak stomach than mutton. The truth is, the proposition is stated too generally, and it becomes necessary to consider the presence or absence of other alimentary principles besides the oleaginous, before it can be absolutely said which articles of diet are best fitted to certain conditions, or to what cause this fitness is to be attributed.

We have been somewhat startled to find Dr. Williams recommending five to seven, p.m., as the dinner hour, and cannot but think his metropolitan habits have been allowed to warp his judgment on this point. It is true he subsequently qualifies his recommendation by saying, that "the practice of dining early, at from one to three, p.m., which is pursued by the majority of persons in the lower and middle ranks of society, would deserve more general adoption on the score of health, were it not generally impossible then to devote the time to it, and rest after it, that the principal meal requires." We do not, however, ourselves see this impossibility; it is the lower and middle ranks of society who are most deeply immersed in indispensable business; and if the higher ranks, who have their time pretty much to themselves, will dispose of it according to certain absurd and arbitrary rules, fixed by themselves, they must take the consequence, but let not the physician yield his assent to any such follies. It is the absolute authority systematically exercised by the hydropathist and homœopathist, in respect to all matters of diet and regimen, which, where benefit is experienced, gives real efficiency to the measures of the one, or preserves from injury the votaries of the other. Provincial physicians well know the state in which the victims of the artificial habits and late hours of metropolitan society come down to the water-establishments; and when these are exchanged for the genuine hygienic conditions, of pure air, exercise, early hours, a clean skin, simple food, the avoidance of fermented liquors, and mental rest, all of which are rigorously enjoined, it is no wonder that the repeated ablutions, both within and without, so diligently practised, (the most tangible point of the treatment, forming indeed the main occupation of the day, and therefore looked upon by the unreflecting multitude as the essence of it,) should be followed by a partial or entire restoration to health, which, in appropriate cases, is nothing more than a necessary consequence of giving up a noxious, and following out a more healthful, general system of regimen. But let not the London physician lend his aid to palliate the bad practices of his patients, but enjoin upon them at once those habits and hours which are the best. Let the luncheon of one to two, p.m., be converted into the dinner of the merchant or the man of business, and his late dinner in the country into what the author of "Modern Accomplishments" terms a "severe tea," taken in the society of his family circle; and let the higher ranks follow the example of the majority of the middle and lower classes in their earlier hours, and we may rest assured that apoplexy, and gout, and dyspepsia, in its Protean shapes, will be less prevalent, and far more easy of management and cure amongst them.

It was our intention to go through, in like manner, the other subjects of hygienics, as here touched upon, by Dr. Williams, but we are warned to desist. It is sufficient to say, that the general tenor of the remarks, brief and hurried as they are, is judicious, and that the entire chapter forms a useful addition to the body of the work.

On the Nature and Treatment of Stomach and Renal Diseases; being an Inquiry into the Connexion of Diabetes, Calculus, and other Affections of the Kidney and Bladder, with Indigestion. By William Prout, M.D., F.R.S., Fellow of the Royal College of Physicians. Fifth Edition, revised. London, 1848. 8vo. pp. 595.

The admirable work of Dr. Prout, on renal affections, notwithstanding the valuable treatises bearing more or less on the same subject, which have been published by Dr. Golding Bird and others, must still be looked up to as the standard work of reference. The short time which has elapsed since the publication of the former edition (the fourth,) renders the present one, on the whole, little more than a reprint of its predecessors.

On turning over the pages, however, we perceive several additions of importance, bringing up the subjects treated of to the present state of our knowledge. To give any further notice of a work so well known and so justly appreciated, would be unnecessary: commendation would be equally superfluous. It is sufficient to announce to all such as may wish to possess the work, that the publication of the fifth edition, just issued, will enable them to do so with the additional advantage of its containing the more recent acquisitions made to our acquaintance with the subjects treated of.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

Returns of Cases treated in the Derby Infirmary during Twelve Months, under Mr. Wright, Mr. Douglas Fox, and Mr. Johnson. Drawn up by Mr. Crossley.

Communicated by Dr. HEYGATE, F.R.S., President of the Association.

* A.—All under this letter were slight cases, a saturnine lotion, with spirits of wine, being applied, many of which were cured by it alone; the remainder were, after a few days, dressed with the following cerate:—
R. Calaminæ, dr. j.; Liq. Plumbi Diacetat., m. xxx.; Unguent. Plumbi Comp., Ung. Sambuci, utrq., oz. ss. M. Fiat Unguentum.

† B.—All of these cases were first enveloped in cotton-wool. Many were serious ones, there being no probability

Burns and Scalds treated in the Worcester Infirmary, from January 1843, to December 1847. The extracts from the Registers made by Herbert Cole, Esq., House-Surgeon.

Communicated by Dr. HASTINGS, President of the Council of the Association.

Treatment.—Cotton wool has been the invariable application, renewed occasionally till the sloughs came off, when the sores were dressed in the usual way, caustic, lint, and chalk pledget over, &c. &c. The application of the cotton has been so successful that we have rarely found it necessary to give opium. We have generally found brandy necessary, and as much milk as they can drink.

of recovery. In those cases which survived, the cotton-wool was renewed, as required, for three or four days, and then a poultice applied to detach it, the cerate as above being afterwards used.

‡ C. A liniment composed of two parts linseed oil to one part turpentine, was first used, being applied by means of cloths kept constantly wet with it, and laid over the injured parts; in one or two days this was discontinued, and they were dressed with the cerate in the usual manner.

The Unguentum Picis, or Unguentum Creosoti, was sometimes used, to hasten the separation of the sloughs. The Cupri Sulphas was used to check too luxuriant granulation. In two cases strips of lint, dipped in a saturated solution of the Cupri Sulphas, were applied, for the same purpose, but created greater pain, without any better result than the sulphate of copper.

The constitutional treatment was the same in each case; an opiate being first given, and after a short interval stimulants, (ammonia, æther, and Camphor,) combined with small doses of Tinctura Opii. When re-eaction commenced a purgative was administered, and followed by mild salines; when sloughing occurred to great extent, tonics, (Cinchona and Quina,) and a good diet, were adopted.

WORCESTER INFIRMARY.—(*Continued.*)

Out-patients from January, 1843, *to December*, 1847.

The continuation of Mr. Crompton's Digest of the Depositions made at Inquests on Cases of Burns and Scalds before the Coroner for Manchester, will be given in the next number.

Foreign Department.

ON DROPSY IN PREGNANT WOMEN.

(Translated from the Archives Générales de Médecine, Fevrier et Mars, 1848. By Thomas Crosse, Esq.)

Among the dropsies which may attack the pregnant woman, some are peculiar to her condition, and to the morbid states which become developed in the course of pregnancy, whilst others are altogether special and subject to the influence of various modifications which the puerperal state effects on the economy.

Dropsy of the cellular tissue in pregnant women may be divided into—

1. Œdema or anasarca, either simple, or complicated with affection of the central organs of respiration and circulation.
2. Œdema or anasarca, with albuminuria.

Gestation produces many changes in the system generally, which may bear upon the causes of these dropsies. Its effect upon the fibrin and blood-globules are well known and need not be here referred to. It affects, however, in a remarkable way, a third element, and one which forms an important part in connection with dropsy, and that is the albumen. The result of analysis shews that the quantity of albumen in the blood varies during the different months of pregnancy. The average quantity in 1000 parts, throughout pregnancy, (from the second to the ninth month,) in the analysis of twenty-five cases, was 67.7. During the seven first months the mean average in fifteen analyses was 68.6. In the 8th and 9th months, in ten analyses, 66.4. We thus find that the blood, during pregnancy, suffers a gradual diminution in the quantity of albumen which it contains, possessing least in the latter months; nor is the quantity of that present so good during this period, it is thinner.

This condition of the blood predisposes to serous effusion; according to MM. Becquerel and Rodier, "the decrease of solid constituents in the serum and albumen themselves" in pregnant women has also some influence upon dropsical formations. When a disease such as albuminuria, becomes added to these various changes, there is greater reason to fear the occurrence of dropsies. The presence of albumen in the urine operates in a certain manner upon the blood of women that are pregnant; analysis has shewn a decrease of albumen to 56.37. In some cases of albuminuria, which had been developed solely in the latter months of pregnancy, apart however from these complicated cases, we consider that the normal decrease of albumen in the blood has a share in the production of these dropsies.

Simple Œdema or Anasarca.—By this term we mean those serous infiltrations, which for the most part occupy the lower extremities of the body — sometimes, though rarely, the upper, and which are neither dependant upon any important organic disease, nor upon the presence of albumen in the urine. The causes which produce them may by divided into general, and local or mechanical. Among the former are general or local congestions, fevers, privations, fatigues, unhealthy habitation; those who are exposed to the inclemency of the weather, and who are of lymphatic temperament, are more likely than others to become affected with serous infiltrations.

Among the local or mechanical causes are the disarrangement in the circulation through the lower extremities, produced by the development of the uterus giving rise to congestion and stagnation of the blood in these parts. This will account for the occurrence of the œdema, and its appearance more especially in the latter months of pregnancy.

The inclination of the uterus to one or other side of the body does not appear invariably to produce œdema in the corresponding limb. In forty cases, twelve times it occupied the limb of the same side, twenty-six times the two limbs equally, and twice the limb of the opposite side; the last peculiarity we have found explained by the position of the fœtus in utero. In a woman, twenty-seven years of age, where there was an inclination of the uterus to the right side, with œdema of the left lower extremity, the head presented with the occiput towards the left side of the pelvis. Eight days prior to her accouchment, when this part engaged with the inferior segment of the uterus, in the hollow of the pelvis, the serous infiltration in the extremity rapidly disappeared.

It is possible that the development of the uterus upwards, by impeding the functions of respiration, and the action of the heart, may give rise to dropsy; but this can only happen when either the development of the uterus is excessive, or the thoracic and abdominal cavities are contracted by rachitis, and even then it does not always occur. The same condition is sometimes produced by the presence of a large fœtus, or of twins, or the existence of tumours about the uterus. The occupation of the individual furthermore influences this disease, the higher classes being less subject to it.

Precursory Symptoms.—We have sometimes seen this œdema preceded by pains in those limbs which afterwards became the seat of it; by giddiness, faintness, pain in the head, palpitations and stoppage of the breath. Sometimes it succeeds the decrease in size of varicose veins. It occurs for the most part in the latter months of pregnancy, though sometimes as early as the third month. We have seen it connected with placenta prævia. It lasts sometimes for days, sometimes for weeks or months, and varies likewise in its bulk and extent. In some cases the effusion is confined to the subcutaneous cellular tissue, while in others it occupies the dermis also. One peculiarity to be noticed in these swellings is their fluctuation in size, apparently the result of certain mechanical causes; the size of the uterus, the position of the fœtus, for instance, for any notable change taking place in them may diminish or remove the œdema. With respect to the urine, it is always diminished in quantity, high coloured and turbid. In the latter months of pregnancy, owing to uterine pressure, it is expelled frequently in small quantities, and is free from albumen, unless there is a co-existing disease to cause it.

Complications.—Varicose veins are frequently seen about the lower extremities and genital organs, preceding in some cases the dropsical effusion. There is never any serous effusion into any of the important serous cavities, nor any gangrene or excoriation of the extremities; they generally terminate by resolution at various periods after delivery, according to the health and strength of the patient. Some have endeavoured, by the theory of metastasis, to connect the occurrence of puerperal peritonitis and fever with the resolution of the effused fluid in the extremities. Our experience is opposed to this theory; in a number of cases that have passed under our observation, we have never observed this phenomenon, except perhaps in a case of effusion complicated with albuminuria, and we are inclined to think, that in those cases where this kind of termination has been observed, the case has not been one of simple œdema, but complicated with some organic affection. One may form a favourable prognosis of these cases. The dropsies with which we may confound these œdemas are—1. Those accompanied with organic affections of the heart and other important viscera. 2. Those dependent upon albuminuria. The former may be distinguished by careful examination of the viscera; the latter by the existence of albumen in the urine. It may be distinguished from phlegmasia dolens, by the pain, colour, and the commencement of the latter at the upper part of the limb.

Treatment.—With respect to the treatment, when the œdema is slight all that we recommend is the avoidance of fatigue, the adoption of the horizontal posture, together with the exhibition of purgatives and non-irritant diuretics. Where it is more considerable, the abstraction of blood in small quantities is beneficial, provided the system can bear it; also warm and vapour baths. We do not recommend bandaging, except in some cases after accouchment, where the fluid is slow in its departure; in some cases a course of tonic medicines (even of steel,) is efficacious.

Dropsies, with Affection of the Central Organs of Respiration and Circulation.—When these complications become added to the pre-existing causes mentioned, the case of course becomes an aggravated one. If dropsy has not presented itself prior to pregnancy, it may now be expected; and if it has done so, it will become increased. Effusion into the large serous cavities may now occur, producing great difficulty of breathing, and even premature labour. In the treatment we observe the same rules as in cases of simple œdema; in addition we may evacuate the fluid by puncture, or incision, or, according to Scarpa, draw off any great quantity that may be effused into the abdominal cavity. If these be not sufficient, it may even be necessary to bring on premature labour.

MEMOIR ON THE LOCALIZATION OF SKIN DISEASES.

By M. Baron.

(Translated for the Provincial Medical and Surgical Journal, from the Gazette Médicale, April 1847.)

The present essay was commenced in the year 1837, at which time the author was "*interne*" to the Hospital of St. Louis. The next year it was presented in competition for the prize annually given to the resident pupils of the institution. At that time the elementary forms and seat of cutaneous diseases had attracted but little attention, and several physicians well versed in cutaneous pathology even advised me then to withhold the present publication, as they considered my data as uncertain, for the reason, that the minute anatomy of the skin was not sufficiently elucidated. Now things are altered, and there is scarcely a dermatologist who does not admit the special localization of skin diseases in the various elementary tissues of the skin. Thus Cazenave ("Annales de la Maladies de la Peau, 1843,) says, that every disease of the skin has a different symptomatic expression, accordingly as it occupies this or that portion of the integumentary apparatus. The same opinion is also maintained by Duparc and Rosenbaum, and by several German and English dermatologists. The author, for this reason, believes that no one has preceded him in his views of the localization of skin disease, and publishes his memoir exactly as it was written ten years ago.

"If," observes M. Breschet, "we could localize skin diseases,—that is to say, if we could, by the aid of anatomy, refer each variety to its special organic seat, we should make a veritable progress in the science of dermatology." This idea the author has taken for his motto, and has endeavoured to give to skin diseases an anatomical development, corresponding to that which has been attained for diseases of other organs. What would be said of the pathologist who, in the present day confounded, under one denomination, inflammation of the peritoneum covering, and of the mucous follicles which line the intestine? Yet this is what is done daily in the consideration of skin affections.

It is true that the intimate structure of the skin was for a long time known, but too imperfectly to allow of a correct anatomical classification of its diseases; but since the researches of Breschet and others, the structure of the skin is as well known as that of other organs. It is therefore full time that the diseases of this important part of the human frame should be studied by the light thus afforded by anatomy.

It must be allowed that the localization of skin diseases is not entirely novel, for Astruc attributed a special seat to tinea, ecthyma, acne. Biett also taught the doctrine, to a certain extent, in his clinical lectures, and Rayer distinguishes between diseases of sebaceous glands and hair follicles. The novelty consists in extending the system thus limited to a few structures.

From the localization of these diseases, arises a classification of their elementary forms, in every respect natural, the principles of which were originally laid down by Bichat, who divided skin diseases into four classes:—1. Diseases of the papillæ; 2, diseases of the

dermoid cellular tissue; 3, diseases of the vascular capillary plexus; 4, diseases of the chorion. This classification, although imperfect, is nevertheless valuable, as indicating a step in the right track.

Before we adduce our own classification, let us briefly recapitulate the different tissues of which the skin is composed. These are—the arterial, venous, and lymphatic plexuses; the papillary bodies; the sudoriparous and sudoriferous apparatus, the secretory apparatus of the epidermis, the apparatus which secretes the colouring matters, the sebaceous follicles, the hair follicles; the matter of the nails, and the cellular fibrous structure. We shall see the diseases which affect these several tissues in the subjoined table:—

1. Diseases of the Vascular Plexuses.—Roseola, rubeola, scarlatina, erythema, erysipelas, vesicatio, pemphigus, nævus, purpura.

2. Diseases of the Papillæ.—Urticaria, prurigo, hyperæsthesia, anæsthesia, elephantiasis Græcorum.

3. Diseases of the Sudoriparous Apparatus.—Sudamina, miliaria, herpes.

4. Diseases of the Apparatus which secretes the Epidermis.—Ptyriasis, eczema, psoriasis, ichthyosis, corns, warts.

5. Diseases of the Chromatigenous Apparatus.—Nævus, lentigo, ephelis, melanopathia, vitiligo, albucismus.

6. Diseases of the Sebaceous Follicles.—Acne disseminata, punctata, rosacea; melitagra; mentagra; impetigo; lupus.

7. Diseases of Hair Follicles.—Lichen, favus, trichoma, alopecia, calvities.

8. Diseases of the Nails.—Onychia.

9. Diseases of the Cellulo-fibrous Tissue.—Ecthyma, rupia, varicella, varioloid, variola, vaccinia, furunculus.

10. Diseases affecting several Tissues.—Scabies.

Frambæsia, molluscum, and keloid, cannot at present be referred to any particular seat.

(To be continued.)

COMMITTEE OF POOR-LAW MEDICAL OFFICERS.

Deputation to Sir G. Grey.

On Tuesday, May 30th, Sir George Grey received, by appointment, at the Home-office, a deputation of poor-law union medical officers, accompanied by representatives from the Royal College of Surgeons of England, the Society of Apothecaries, the Provincial Medical and Surgical Association, and the National Institute of Medicine, Surgery, and Midwifery. The deputation was extremely numerous, several gentlemen having come from the country at great distances to be present; but, to meet the convenience of Sir George Grey, the statements of the deputation were addressed to him personally by the following gentlemen:—Benjamin Travers, Esq.; Edward Stanley, Esq.; Edward Bean, Esq.; John Ridout, Esq.; Dr. Cowan, of Reading; Dr. Hodgkin; Dr. Burton, of Walsall; J. Pearson, Esq., of Woolton, near Liverpool; William Cantrell, Esq., of Wirksworth, Derby; Edward Daniell, Esq., of Newport Pagnell; Peter Martin, Esq., of Reigate; Jas. Stedman, Esq., of Guildford; James Vallance, Esq., of Stratford; George Ross, Esq.; T. Piers Healey, Esq., (hon. sec.) The other gentlemen present were Thomas Parker, Esq., Woburn; B. Eddison, Esq., Nottingham; George Bottomley, Esq., Croydon; T. H. Smith, Esq., St. Mary's Cray; Edward Boulger, Esq., Bletchingley; A. Barnett, Esq.; C. F. Lord, Esq.; William Lobb, Esq.; James, Mitchell, Esq.

Dr. Hodgkin introduced the deputation to Sir George Grey.

Mr. Travers, the President of the Royal College of Surgeons, stated that he appeared there, with his colleague, Mr. Stanley, by appointment of the council of the college, to give the weight and sanction of that body, *tale quale*, to the representations to be addressed to him by the Convention of Medical Poor-law Officers. The council were most happy to bear testimony to the high respectability of the gentlemen composing the committee of that body, most of whom were members of that college he represented; and they desired further to say that, without pledging themselves to the minor details contained in the suggestions of the committee, they were strongly of opinion that the prayer contained in the memorial was based on facts which unfortunately could not be denied, and which, for the comfort and content of the poor, as well as for the respectability of the profession, ought no longer to be allowed to exist.

Mr. Bean, the Master of the Society of Apothecaries, and Mr. Ridout, one of the Wardens, in warm terms, urged similar recommendations on Sir George Grey, on behalf of their corporation, and were followed by Dr. Cowan, of Reading, deputed to represent the Provincial Medical and Surgical Association.

Dr. Burton, of Walsall, then entered upon a general statement of the grievances complained of, urging first the necessity of a stricter inspection of the local operation of those portions of the poor-law regulating medical relief. In many cases, but more especially those strictly medical, he contended there was a necessity that the inspector should be a man of medical education, in order to decide whether the intentions of the Legislature were fulfilled. The great defect of the poor-law, especially in regard to medical men, was, that its enactments, even when favourable to them, could not be enforced in local districts, in consequence of the pertinacity of poor-law guardians in some cases, and the ignorance of non-medical commissioners as to the various ways in which their orders may be evaded or successfully obstructed in others; he, therefore, thought it a most important and cardinal point that there should be medical inspectors, understanding the nature of medical officers' rights and duties, and seeing both of them enforced.

Sir George Grey here interposed, stating that this point was already under consideration; and that in Ireland, where a medical man had been appointed

assistant commissioner, without any particular district being assigned to him, being, therefore, at the service of the commission in medical inquiries generally, the result had been most satisfactory.

Upon this admission, Dr. Burton proceeded to point out the mischiefs arising from having appointments frequently held by an annual tenure. With the fear before him of dismissal without cause assigned, the medical man could not do his duty to the poor either comfortably or independently. A further point urged was the extremely low rate of remuneration received for medical services under the poor-law. Owing to the degradation of that rate, the medical officers received a sum which barely covered the cost of drugs and medical appliances, nothing being left to remunerate the union surgeon for his loss of time, and for the exercise of his skill, &c. There was also this anomaly in the mode of payment, that while in a few cases as much as sixteen shillings were paid, in the vast majority the payment was of a very insignificant character, indeed, reaching below sixpence each case—a most conclusive proof that there was an utter want of system and of efficient supervision in the adjustment, if so it could be called, of medical remuneration; and that in these matters the poor-law guardians acted pretty much as they pleased, according to their own caprices, notwithstanding the existence of a central authority.

Sir George Grey remarked that it was the peculiarity of the poor-law to unite the two principles of local management and central superintendence, and the evils complained of were the consequence. It certainly was a matter of very great difficulty to conciliate the arrangements on a uniform plan, with that liberty of local action which formed a characteristic of English government.

Mr. Healey submitted that the central authority was entitled to take a more prominent part in this matter than in the subject of poor-law administration generally, as Government had guaranteed to pay half the poor-law medical expenses from the Consolidated Fund.

Sir George Grey observed that the Government could not lose sight of that view of the case. The same principle had regulated their proceedings in reference to the educational grant, in the cases of schools benefitted by it, and there was no doubt that the Government were bound not to neglect an advantage of the kind referred to.

Mr. Peter Martin, of Reigate, then called the attention of Sir George Grey to the fact, that the utter inadequacy of medical remuneration under the poor-law was now universally confessed by every intelligent person identified with its administration; that it never could have descended to such a disgraceful rate if a system of advertisements and tenders had not been generally adopted, by which, in many cases, the poor were transferred to the care of young men and strangers, and in others, old practitioners, compelled in self-defence to submit to receive salaries entirely inadequate to their labours, duties, and expenses. The evils of this tender-system had, in fact, proved so frightful and unjust that, by the general voice of public opinion, the commissioners were obliged to put an end to it; but, though this was the fact, the great evil originating from the abuse, viz., low remuneration, had still been perpetuated. As a proof of the change in public feeling on this subject, Mr. Martin mentioned that a case had recently occurred in the Guildford union, in which it had been considered necessary to summon a jury, who, without attributing any blame to the medical officer, had found, as a part of their verdict "that the medical officer ought to have a sufficient salary to enable him to keep a horse."

Mr. Stedman, of Guildford, confirmed this statement, and said that the surgeon so ill-remunerated was a stranger to the neighbourhood, and had accepted the appointment after it had been resigned or declined by all the surgeons residing in that locality, because of the pecuniary losses it entailed on its possessor.

Mr. Vallance, of Stratford, pressed for an early attention to this subject, which was not of less importance to the content and well-being of the working classes than of the medical profession, and said that it was not pleasant nor useful for the public to know that the average payments of attendance on prison patients was 13s. 6d., while that of union patients did not exceed one-tenth of that sum.

Some conversation also occurred as to the system of supplying drugs by the unions; but it was shown that the practice was rare, far rarer than Sir George Grey imagined; that where it had been tried it was found to double the expense of poor-law medical attendance, and that there was little hope of accomplishing so great a change.

Mr. Daniell, of Newport Pagnell, adduced in particular his own case, where the ordinary drug price, as charged by a chemist for drugs as supplied by him, had been proved nearly to double the whole salary, and in consequence of which low remuneration, or rather no remuneration, he had felt compelled to resign.

Sir George Grey stated that the question of expense was one subordinate to what was necessary to secure efficient medical relief; the deputation might be assured of the interest he felt in the matter, although the subject more immediately belonged to the department of Mr. Buller, the president of the poor-law commission, with whom he would confer upon it.

The deputation then withdrew, acknowledging the courtesy with which they had been received.

ON THE DOCTRINES OF HOMŒOPATHY.*

The frequent and large doses of drugs ordered into the stomach, an organ destined by nature only for the digestion of food, which function must, of necessity, either permanently, or for a time, be impaired thereby, by practitioners in times past, and by some I fear in the present day; the poisonous nature of many, such as arsenic and mercury, which are introduced into the system with a heroism truly surprising, considering the present state of our knowledge of physiology and chemistry; the pervading nature and consequent and lasting action of these substances on the whole frame;

* Continued from page 217.

the freedom with which venesection has been resorted to—a practice, I am happy to say, of late years much abated:*—Taking, I say, these things into consideration, it is no wonder that patients should have sought relief from such a depressing and destructive system, by rushing to the protection of some homœopathic doctor, who would relieve their disorders through the operation of faith, imagination, and globules.

Another element in the apparent success of these doctors, no doubt consists in their attention to diet and regimen, which the members of the "old school" have in times past too much disregarded. I have carefully studied their directions on this subject, and I must confess, although I do not see the advantage of all their prohibitions, they appear perfectly consistent with health, and rational. One circumstance I may remark on incidentally, that they exclude the use of alcoholic drinks generally, at least, during the treatment of a disease. This appears to be an error, (entertained by them in common with another sect—the Teetotallers,) the more to be wondered at, considering the light which modern chemistry has thrown on this subject. Liebig has asserted, and, as I think, notwithstanding attempted refutations, proved, that alcoholic drinks, such as beer, wine, and spirits, may, in perfect consistence with health, form a material portion of our food, being, as he calls them, "elements of respiration." I would ask, should a traveller, benighted in some cold region, have the option of a flask of wine or spirits, a loaf of bread, or a beef steak, supposing each of equal weight, to form his sustenance for a given time, which would he choose? I think undoubtedly the first; and why? because it would supply that essential of life, animal heat, most rapidly, and by affording, most readily, carbon to the system, would best prevent the action of the oxygen of the atmosphere on the materials of the body. I do not mean that he would reason thus, but that his instinctive feelings would lead him to the choice. If such arguments are applicable in an extreme case, why may not vinous fluids be employed, of course, in moderation, consistently with health, as an article of common and ordinary diet.

There is, I believe, no general condemnation of the *use* of wine in any part of the Holy Scriptures; on the contrary, it is frequently alluded to as a blessing†—one awarded to the most highly-favoured lands. It is spoken of as "making glad the heart of man," an effect contributing, doubtless, to the health of both body and mind, but one quite disregarded by the cold and utilitarian reasoner of the teetotal and homœopathic schools.

Paley has remarked, while comparing the mechanism of the human frame with that of a watch, that the former has this very decided advantage over the latter,—viz., that it can in many cases control and regulate its own actions so far as to be able to restore them to order, when by any cause or accident they may have become disordered—a fact, I humbly suggest, too much overlooked by our profession generally. I hope by this observation I shall not be suspected of belonging to that class of "medical sceptics" which has arisen lately, and who appear to advocate the maxim, "every man his own physician," or at least to argue, that when the physician *is* called in, he has little to do but watch the *vis medicatrix naturæ*; or, in other words, to study, as they call it, "the natural history of disease." A strange phrase truly. A type of this class of practitioners may be found in the gentleman quoted by Dr. Forbes, who, speaking of homœopathy, boasted that he had beaten the practitioners of that school, for while they had been curing their patients with infinitesimal doses, he had been curing his, for the last two years, with *nothing at all.*

I do not see why we should all at once be called upon to renounce the wisdom and experience of our ancestors, in the application of drugs and medicaments: we have the authority of all ages and nations for their employment, and for some we have the accumulated evidence of centuries as to their beneficial effects in certain states of the system. Would it not be better to follow the counsel of the wise man, who says:—"The Lord hath created medicines out of the earth, and he that is wise will not abhor them. With such doth he heal men, and taketh away their pains." Another wise man has said:—

> "O! mickle is the powerful grace that lies—
> In plants, herbs, stones, and their true qualities."
> Rom. and Jul., ii., 3.

I cannot better conclude these brief remarks on the doctrines and practices of homœopathy than by quoting the last paragraph of some excellent remarks on the subject, by the able President of our College of Physicians:—"That amongst the credulous public, a train of knight-errants should be found to enter the lists against science and common sense, is not so extraordinary; but that any professional man, of ordinary education and honesty, should present himself as the defender of a doctrine that contradicts all facts, and confounds all opinions, is wholly unaccountable." "But cures have been performed through its means." True; but on whom? On hypochondriacs who have been drenched for years with physic, and to whom this system has brought a truce, while it has encouraged their faith through the medium of the imagination.—*Paris' Pharmacologia*, edit. 9, p. 55.

---

* I remember a late physician saying in his lecture—"Gentlemen, the lancet is the sword arm, and mercury is the shield arm of our profession." Too much, I fear, may the former, from its abuse, be regarded as a destructive weapon, while the latter may not inaptly be compared to a shield, having so frequently been employed to shield the ignorance of a practitioner.

† Wine is as good as life to a man, if it be drunk moderately; what is life then to a man that is without wine? for it was made to make men glad.

* Wine, measurably drunk, and in season, bringeth gladness of the heart, and cheerfulness of the mind.—Ecclus., Chap. xxxi., ver. 27 and 28.

Give strong drink unto him that is ready to perish, and wine unto those that be of heavy hearts.—Proverbs xxxi., ver. 6.

General Retrospect.

PRACTICAL MEDICINE.

TETANUS CURED BY CHLOROFORM.

Mr. Baker reports the case of a man who had a finger jammed in machinery. On the fifth day he received a very urgent message, stating that he had had no sleep since he saw him, and that he had been dying since two in the morning, and he was requested to meet Dr. Bell Fletcher. At eight oclock he visited the patient with Dr. Fletcher. They found him perfectly stiff with tetanic spasm. He appeared conscious. but had lost all power of articulation and deglutition, The whole surface of his body was bathed in perspiration; every muscle seemed implicated in the spastic action; indeed, he had all the ordinary symptoms of traumatic tetanus, and no hope was entertained of his recovering from this condition. They ordered a turpentine enema to be administered immediately, and the tincture of cannabis sativa to be given in doses of twenty minims every three hours; and thinking it a favourable case for the application of the chloroform, it was arranged that it should be administered on the next visit. At two p.m. Mr. Baker again saw him, and found him in the same state in which they left him in the morning. The attendants could not get him to swallow the medicine, and made ineffectual attempts to give a glyster. Under these circumstances he administered the chloroform on a handkerchief, and in about three minutes the muscles began to relax. The thumb which had been firmly grasped by the fingers into the palm, became quite easily moved; for a short time he muttered incoherently, then answered two or three questions rationally, and finally sank into a sound sleep, with the muscular system relaxed and free from convulsions. Mr. Baker kept up the effect of the chloroform for three quarters of an hour, and left him asleep, having prescribed a blister to be applied to the back of the neck, and two grains of calomel every two hours, to get free action of the bowels. At nine p.m. he again visited him, and learned that an hour after he had left him the patient awoke, as if from sleep, with the free use of his limbs restored, and asking to be assisted to the night-chair, where he had a copious stool, and entered into rational conversation with those around him. From this time his general health gradually improved; but the finger continued much swollen. Finding, on the 3rd ultimo, that the pain had increased, with slight muscular convulsive twitches, and thinking that the finger might be the cause of irritation, and, consequently, being fearful of a return of the tetanic symptoms, Mr. Baker determined to remove the finger at once. Not having the chloroform with him, he amputated it without its use; and since its removal there has been no return of the convulsive symptoms, and the patient is doing well.

The tetanus came on five days after the accident, and the finger was amputated on the eleventh day after the original injury, and six days after the successful administration of chloroform.—*Lancet*, June 3rd.

TREATMENT OF ASPHYXIA.

Dr. Reid, of Liverpool, suggests, that in treating the apparently asphyxiated, a certain proportion of chlorine or nitrous oxide should be used with the atmospheric air employed in artificial respiration. He is led to propose this on the principle that the chief object is, independent of restoring the circulation and temperature, that the dormant irritability should be subjected to an extraordinary stimulant. While the common atmospheric air, or even oxygen gas perfectly pure, has no action, the irritative action of this gas, (the chlorine,) so well known in the living subject, will, in a corresponding manner, be more energetic in the lungs of the apparently drowned. In numerous experiments made on the healthy subject, and also on several different invalids, he has found that in the former, on an average of about 200 individuals, one cubic inch of chlorine, diffused through 200 cubic inches of air, (common air,) could be respired without exciting any irritation; but when the quantity of atmospheric air was reduced, the amount of chlorine remaining the same, more or less irritation was induced. It is unnecessary to remark on the different effects on invalids, as these varied very much, and it would be impossible to make nice applications of the sort in cases of asphyxia.

One cubic inch of chlorine may be diffused through fifty cubic inches of air for this purpose, or even one cubic inch in twenty-five cubic inches of atmospheric air. The respiratory movements once being excited, the amount of chlorine may gradually be reduced. Scarcely any bad effect will supervene which cannot be relieved by ammonia and hot water. The chlorine is readily obtained from the common chloride of lime.—*Lancet*, April 22nd.

SURGERY.

UMBILICAL HERNIA IN CHILDREN.

Mr. Spong, in speaking of the treatment of this disease, says:—Well regulated, constant, and equable pressure, seems all-sufficient for the cure of this disease in infants, and the elastic belt, presently to be described, answers the purpose effectually. It consists of a piece of vulcanized caoutchouc, about six inches in length, and three inches and a half in breadth, to either end of which is attached a piece of fine white linen web, (a species of girthing, used by saddlers, and manufactured of about the same breadth,) with tapes appended, which are tied behind the back. The piece of vulcanized India-rubber should be of such a length, according to the size of the child, as will embrace rather less than one-third of the circumference of the abdomen, the circle being completed by the pieces of linen web. This material is sufficiently stiff to prevent its creasing; its elasticity admits of the various movements of the child, its crying, coughing, &c.; and in whatever position the body is placed, it ever keeps up a determinate pressure. The patient soon becomes accustomed to its use, and it may be worn advantageously by night as well as by day; moreover, it retains its position accurately.

This substance is made of various degrees of thickness; that which is about as thick as half-a-crown will

be found to answer best. Another small circular piece, twice as stout as this, and about two inches in diameter, should be fixed to the centre of the first by a stitch of strong silk passed through the centre of both; this acts well as a pad immediately over the hernia. The curve of this malposition of parts is speedily effected by Nature, and the ring becomes accurately closed, provided the hernia is well maintained. Any requisite degree of pressure can be attained by means of this belt, on approximating the tapes, three or four in number, on each side. On one side they should not be attached close to the end, in order to allow of overlapping when the caoutchouc is put upon the stretch.

This instrument will be found both simple and efficient, and it costs but a few pence—a point of some consideration in the treatment of the poor. I have tried its use in several cases, and with uniform success. The cure usually occupied a period of from three to four months; but in one case, where, from neglect of the mother, the hernia had attained the size of the child's fist, the use of the belt was required for six months. The same belt, made of stouter material, will be found to answer for reducible umbilical hernia of adults, as the instrument is not displaced by exercise, and the patient can employ whatever amount of pressure he finds best for his particular employment.—*Lancet*, June 3rd.

OBSTETRIC MEDICINE.

CHLOROFORM IN MIDWIFERY.

Dr. Murphy concludes as follows from his experience of the action of chloroform in labour:—

1st. It does not interfere with the action of the uterus, unless it be given in very large doses, which is never necessary.

2nd. It causes a greater relaxation in the passages and perinæum; the mucous secretion from the vagina is also increased.

3rd. It subdues the nervous irritation caused by severe pain, and restores nervous energy.

4th. It secures the patient perfect repose for some hours after her delivery. These three last effects consequently render an operation much easier to perform, and the recovery of the patient afterwards much more favourable.

5th. The order of its effects on the vital functions seems to be, loss of sensation, partial loss of voluntary motion, loss of consciousness, complete loss of voluntary motion, stertorous respiration, loss of involuntary motion, cessation of the action of the uterus, of respiration, of the action of the heart.

6th. Its injurious effects, when an ordinary dose is given, seem to depend upon constitutional peculiarities, or on improper management. Much excitement about the patient may render her violent. Catalepsy has occurred in some; clonic contractions in others. Some patients are slow in recovering from the effects of a large dose; they remain giddy during the day, and sometimes faint when they stand upright.

PUERPERAL CONVULSIONS: INHALATION OF CHLOROFORM.

M. P——, aged 22 years, was admitted into the Hôpital St. Louis on the 24th of February, at eight o'clock in the morning. Labour had set in the preceding evening, and the patient had already had convulsions, which had necessitated venesection. Before she was brought to the hospital her constitution was lymphatic, and her habit stout and full.

When the surgeon arrived, the patient was in a state of convulsion, and completely unconscious; the face was swollen, the lips purple, and froth issued from the mouth; the fit lasted one minute after M. Richet first saw the patient, when, having examined per vaginam, he recognized a presentation of the head, which was gradually descending into the pelvis. The attacks succeeded one another with rapidity; the respiration was hurried, stertorous, and the pulse small, frequent, and irregular.

In the intervals, the loss of consciousness was still complete the teeth were set, the hands firmly closed. Chloroform was exhibited at the beginning of each convulsive fit, the duration of which was materially shortened by the inhalation, although their return was equally frequent during the two hours which followed. At half-past two o'clock, parturition was completed, and a large, well-developed boy brought forth; delivery was immediately accomplished. The patient gradually improved during the following days, and left the hospital on the 5th, with a tendency to mental derangement.—*Revue Médico-Chirurgicale.—Medical Times*, April 1st.

PHARMACY.

NEW PROCESS OF PREPARING IODIDE OF POTASSIUM.

By M. Criquelion.

Slake forty parts of quicklime with water, and add twenty-four parts of iron filings to make a complete mixture; add ninety-four parts of iodine by degrees, so as to avoid a too violent action, and let the mixture be stirred the whole of the time.

Should the reaction be too strong, its effect may be reduced by slight additions of water. Triturate the mixture until paper previously imbued with starch does not turn brown by contact with a slight trace of the liquid, but only shows an ochreous spot. Then throw the whole on a filter, and wash it until the water which passes through the filter gives no precipitate on the addition of acetate of lead. The waters which have passed through the filter are now mixed together, and treated with a solution of carbonate of potash, until the liquor gives no further precipitate. Filter well the deposit of calcareous carbonate, and a perfectly colourless solution will be obtained, which may be evaporated and crystallized in the ordinary manner. Ninety-four parts of iodine furnish by this process 119½ of iodide of potassium, perfectly white and pure. The difference of 3½ per cent. between the actual product and that given by theory (123,) results from the greater or less state of purity and dryness of the iodine employed.

When the iodine is first triturated with the iron and the chalk, the mixture acquires a brownish colour, and when the action has ceased it has acquired the ochreous colour of peroxide of iron. The filtered liquor consists entirely of iodide of calcium, without the least trace of iron, so that by double decomposition a pure
